

# **Foreword**

Since 1971, the National Statistics Institute has carried out a quality evaluation programme of the Economically Active Population Survey. Its purpose is to make information available regarding sampling errors and errors not related to sampling, which allows, one the one hand, to make opportune decisions on the perfection of the methods, and on the other hand, to provide the user with information regarding the quality of the data offered.

Following a brief interruption in this programme in the year 2005, as a result of the implementation of a new information collection method, the current publication offers the results obtained in the year 2007, linked with the previous publications on quality evalution of the Economically Active Population Survey.

The National Statistics Institute would like to express its gratitude to the families that have provided the information requested, and to all of the persons who have been involved in carrying out this work.

**Jaume García Villar**

INE President

# Introduction

On evaluating the quality of the results of statistics, the goal is to achieve two fundamental objectives:

- To detect the errors that have been produced during the different stages of their compilation.
- To provide users with detailed information regarding the quality of the data that they deal with.

The detection of the errors produced should not be reduced to a mere numerical presentation of them. The primordial objective should be their analysis, in order to decipher the possible causes of their origin. This is important, even essential, in all statistics, so as to improve the quality thereof. Continuous surveys such as the Household Budget Survey (HBS) also include the attraction of the immediate collection of their results, avoiding in parallel the deterioration of the quality of all of the routine work that this type of survey entails. To reduce the errors unrelated to sampling allows us to improve the quality of the estimates, for the purpose of obtaining acceptable levels of error, and maintaining them over time, which allows for a more adequate study of the resulting time series.

On valuing the results of an evaluation program, it is necessary to bear in mind the conditioning factors under which the surveys are conducted, which prevent, in many cases, evading the errors later detected in the evaluation, with the compilers of the statistics still being conscious of the possibility of their presence. However, the supply of the information on the limitations of the data is an unavoidable duty, since an inappropriate use of the figures can cause the failure of socio-economic and demographic plans and projects, and falsify conclusions on measures developed by politicians, economists and the remaining users of the statistics.

In the APS, the quality evaluation has been extended in successive phases to the different phases of the survey, currently constituting one of the most complete evaluation programmes worldwide. The information obtained has been used to introduce amendments to the methodology applied, aimed at improving data quality. The user is provided with results of the evaluation of varying lengths in three types of publication: quarterly in *Main Results and Detailed Results* and annually, in monographic reports such as this one, dedicated exclusively to data quality.

The present volume offers the data regarding the quality of the survey for the year 2007.

# 1. Quality of the data

The errors that affect the entire survey can be grouped into two large classes:

- **Errors due to sampling**, caused by obtaining data via samples.
- **Errors unrelated to sampling**, which are common to all statistical research, whether the data is obtained via sampling or via census.

Chronologically, the first objective of the statistics interested in the subject, from both theoretical and practical points of view, has been the calculation of the sampling error by the estimators. The importance of the calculation methods of the sampling error reside in the following fact: knowledge thereof enables, on the one hand, limitation within the confines of a confidence interval the real value of an estimated parameter, and on the other, quantification of design efficiency as per the aforementioned parameter; moreover, its analysis enables the statistician to choose the most efficient design from a series of alternatives, taking into account the resources available.

The natural indicator of the accuracy of an unbiased estimator is its standard deviation, since with a given design, an unbiased estimator is more accurate, the more possible estimates are concentrated around the actual value. Accuracy increases with sample size, although design features also influence this: stratification, hierarchy of sampling units, selection method, etc., and the nature of the variables studied. The size of the sample is limited by the resources; the design is limited by the availability of basic structural information; and the nature of the variables is an element, which cannot be acted upon.

The errors other than sampling errors may occur in any of the phases of the statistical process: before collecting the data, during the information collection and in the operations subsequent to collection, it being possible to group data as actual fieldwork errors and otherwise. We may include among the former, among others, errors in collecting information, whether due to deficiencies on the part of agents or on the part of unsuitable informants, incorrect statements or non-response. Included in the second are framework deficiencies, inadequacies in definitions and questionnaires, encoding or recording errors, etc.

The study and application of statistical methods for assessing errors other than sampling errors, and the subsequent measuring of their influence on the end results, being more recent than that relating to sampling errors. One of the procedures followed in order to assess data quality, and which is applied in the APS, consists of repeating the interview, shortly after having carried out the original interview, with part of the surveyed units. Through the comparison of the data collected in both interviews for the same units, it is possible to estimate the quality of the results, and provide the users with some numerical indices regarding the same. This procedure is based on the model by Hansen, Hurwitz and Bershad, applied by the United States Census Office.

In relation to this model, it is appropriate to mention that more progress has been made in individualised analysis of the influence of certain factors giving

rise to errors and in applying controls and imputation methods for resolving them, than in evaluating the overall effect of sampling errors and non-sampling errors on the results. The first line contains evaluations carried out by the INE in the APS.

In the following sections of this report, the different types of error are analysed individually, showing the methodology applied for evaluating them.

## 2. Sampling errors

### 2.1 Methodology

In the successive semisamples method is applied for calculation for errors, which enables estimation of the variance of an estimator  $\hat{X}$  by means of the formula:

$$\hat{V}(\hat{X}) = \frac{1}{r} \sum_i^r (\hat{X}_i - \hat{X})^2$$

where:

r is the number of repetitions used

$\hat{X}_i$  is the estimate obtained with the i-th repetition

$\hat{X}$  is the estimate obtained with the complete sample

Each repetition is a subsample composed by a number of sections equivalent to 50 per cent of the complete sample. The number of repetitions used in the APS has been set at 40. In order to form them, sections of each stratum are grouped into pairs, and the first section of each pair is randomly assigned to 20 repetitions, and the second to the remaining 20. Thus, each section appears in half the repetitions and the number of sections in each repeat is equal to 50 percent of the complete sample.

This repetition structure remains indefinitely, thus enabling calculation of the sampling error of any survey estimate without further programming problems, in theory, than applying 40 times the same formula of the estimator used in the survey, and finding the mean square of the values estimated on the basis of the 40 repetitions as compared with the estimate based on the complete sample.

Calculation of the estimates taken from the semisamples is carried out in the same way as with the full sample, in other words, by means of a ratio estimator calibrated by age group and sex and population total by province.

---

### 2.2 Presentation of sampling errors

In the tables of this document the sampling error is presented as a variation coefficient, in other words, expressed as a percentage of the estimate, with the following formula:

$$C\hat{V}(\hat{X}) = \frac{\sqrt{\hat{V}(\hat{X})}}{\hat{X}} \cdot 100$$

Variation coefficients have been calculated for the following characteristics:

#### **National level**

- 1) Population age 16 years old and over by age group and sex (table E.M.1)
- 2) Active persons by age group and sex (table E.M.2)
- 3) Active persons by branches of activity and sex (table E.M.3)
- 4) Unemployed person by economic sector and sex (table E.M.4)
- 5) Active persons by age group and sex (table E.M.5)
- 6) Employed persons by economic sector and sex (table E.M.8)
- 7) Employees persons by economic sector and sex (table E.M.9)
- 8) Persons employed part-time by economic sector and sex (table E.M.10)
- 9) Unemployed persons who have worked previously having stopped working less than 36 months ago, by reason for having left their last job by sex (table E.M.11)
- 10) Potential Active Population by reason for not seeking employment and sex (table E.M.12)
- 11) Inactive persons by type of inactivity and sex (table E.M.13)

#### **Autonomous and provincial level**

- 1) Population aged 16 years old and over, by sex and relationship with the economic activity by province (tables E.M.6)
- 2) Population aged 16 years old and over, by sex and relationship with the economic activity by Autonomous Community (tables E.M.7)

Data provided in these tables makes it possible to have an approximate idea of the reliability of the different survey estimates. In general, the greater the level of breakdown of the figures, the greater the resulting sampling error, and therefore the lesser the accuracy of the estimate.

---

## **2.3 Use of tables**

When calculating and publishing the sampling error, the statistician provides the user with a means of obtaining a numerical interval that has certain confidence (measured in probability terms) of containing the real value that we wish to estimate.

Sample theory determines that, in the interval between the estimate less twice the absolute sample error and the estimate plus twice the absolute sample error, there is 95% confidence in finding the real value or parameter that we want to estimate. From here on this interval is called the *95% confidence interval*. It may be interpreted that, on average, of each 100 samples obtained under the same design and general conditions these confidence intervals obtained from each sample will contain the real value 95 times out of a 100.

From the estimate of a certain characteristic and its sample error other confidence intervals may be formed with similar interpretation, for example:

estimate  $\pm$  1 times the sample error = confidence interval of 67 percent.

estimate  $\pm$  2 times the sample error = confidence interval of 95 percent.

estimate  $\pm$  3 times the sample error = confidence interval of 99,7 percent.

For example, the estimate of the total inactive person in the second quarter of the year is 15,464,600 with a relative sampling error of 0.27 percent. This means that there is a great deal of confidence, measured in probability terms confidence of 95 percent, of which the real value of the total unemployed persons will be within the interval between 15,381,092 and 15,548,108 (that is,  $15,464,600 \pm 2 \times 41,754$ ).

It can be concluded that it is up to the user to determine whether or not a figure with a certain sampling error is useful to him or her for making decisions, in accordance with the degree of reliability needed for this.

The magnitude of relative sampling errors may invalidate certain provincial estimates; nevertheless, the latter may be useful if grouped by Autonomous Community in accordance with the needs of each user. In these cases, an estimate of the relative sampling error may be obtained by means of the formula:

$$\hat{CV}(\hat{X}) = \frac{1}{\sum \hat{X}_h} \sqrt{\sum (\hat{X}_h \cdot \hat{CV}(\hat{X}_h))^2}$$

where:

$\hat{CV}(\hat{X})$  = estimate of the relative sampling error in the Autonomous Community.

$\hat{X}_h$  = the estimation of characteristics in the h-th province.

$\hat{CV}(\hat{X}_h)$  = estimate of the relative sampling error in the h-th province,

with the sums extended to all provinces in the Autonomous Community.

In tables E.M.7 the corresponding relative sampling error are presented for the Autonomous Communities as a percentage.

### 3. Non-response

In the APS, the dwellings selected remain in the sample during six consecutive quarters, after which they are replaced by other dwellings from the same section.

In order for there to be a considerable amount of common sample between two consecutive quarters (5/6 of the sample), replacement of dwellings with others is staggered, whereby each quarter 176 of the sample is renewed, the part corresponding to dwellings which were in the sixth interview the previous quarter. In order for this process to be easy to carry out, the sample of dwellings is distributed into six parts or *rotation shifts*, such that each quarter the dwellings corresponding to a rotation shifts are renewed.

In dwellings corresponding to the rotation shift in the first interview, solely the CAPI collection method is used. In dwellings corresponding to shifts that are in second and successive interviews, the CATI method is used primarily, only leaving for CAPI dwellings without a telephone and those that, even though they have a telephone number, prefer to continue with the personal interview method in successive quarters. In other words, whereas the CAPI method is used in all interviews, the CATI method is only used in second to sixth interviews (subsequent interviews).

The dwellings selected for the sample (incumbent households), according to the situation they are in at the time of interview, are classified into three types:

- **Unavailable dwellings:** in CAPI those dwellings which are unreachable for conducting the interview are included under this designation, generally due to climatological causes (snowstorms, floods, etc.) or geographical caused, where there are no when there are no routes to arrive there.  
In CATI those dwellings for which, despite having a contact telephone number, including those having been interviewed previously via the CATI system, it is not possible establish telephone contact, however much the calls are repeated, or obtain another contact number under this designation. Under these circumstances, attempts are made to interview the dwelling via the CAPI method, but if there is no longer enough time, they are ultimately classified as inaccessible, and are passed to CAPI for the second quarter.
- **Unsurveyable dwellings:** these are those dwellings that do not belong to the group being studied, due to not being used all year or most of the year as a habitual or permanent family residence. Included within this type are empty dwellings, secondary or seasonal dwellings, those intended in their entirety for purposes other than those of a family residence and those dwellings that are unreachable at the address shown on the work report (the latter are only possible in CAPI).
- **Surveyable dwellings:** these are the ones that are used the whole year or a large part of it as a permanent family residence. Within this type there are cases in which data cannot be obtained from the occupants of the dwelling due to absence or refusal thereof to participate in the survey. These cases constitute what is known as *lack of response*.

**Chart 1.1** shows the total number of dwellings selected in the four quarters of the year, broken down into the three types mentioned.

**Charts 1.2 and 1.3** show the breakdown of selected dwellings, according to the collection method used, CATI or CAPI.

Processing, within the general process of the survey, of *unsurveyable* dwellings and of dwellings on whose occupants no information is obtained (non-response) differs significantly due to the characteristics and influence on the estimates of both types of incidence, as can be seen below.

## 1.1 Selected dwellings. Total

Dwellings	Quarter									
	First		Second		Third		Fourth			
	No.	%	No.	%	No.	%	No.	%	No.	%
Total	79,768	100.00	80,474	100.00	81,153	100.00	81,764	100.00		
- Unavailable	1,145	1.44	1,096	1.36	1,109	1.37	1,162	1.42		
- Unsurveyable	12,647	15.85	12,930	16.07	13,208	16.28	13,629	16.67		
- Surveyable	65,976	82.71	66,448	82.57	66,836	82.36	66,973	81.91		

## 1.2 Selected dwellings. CATI

Dwellings	Quarter									
	First		Second		Third		Fourth			
	No.	%	No.	%	No.	%	No.	%	No.	%
Total	48,720	100.00	49,344	100.00	49,488	100.00	49,186	100.00		
- Unavailable	1,070	2.20	1,026	2.08	1,023	2.07	1,097	2.23		
- Unsurveyable	1,040	2.13	1,011	2.05	929	1.88	871	1.77		
- Surveyable	46,610	95.67	47,307	95.87	47,536	96.06	47,218	96.00		

## 1.3 Selected dwellings. CAPI

Dwellings	Quarter									
	First		Second		Third		Fourth			
	No.	%	No.	%	No.	%	No.	%	No.	%
Total	31,048	100.00	31,130	100.00	31,665	100.00	32,578	100.00		
- Unavailable	75	0.24	70	0.22	86	0.27	65	0.20		
- Unsurveyable	11,607	37.38	11,919	38.29	12,279	38.78	12,758	39.16		
- Surveyable	19,366	62.37	19,141	61.49	19,300	60.95	19,755	60.64		

### 3.1 Unavailable dwellings

In the preceding paragraph the circumstances have been described, which must occur together in a dwelling in order for it to be considered inaccessible. As aforementioned, this type of dwellings may appear either where data is captured using CAPI, or where this is done using CATI.

In the case of unavailability in CAPI, the interviewer waits for the causes of this to disappear, in order to be able to access the dwelling and conduct the interview, insofar as the duration of work on the section allows for this. Otherwise the dwelling is finally considered inaccessible and revisited the following quarter.

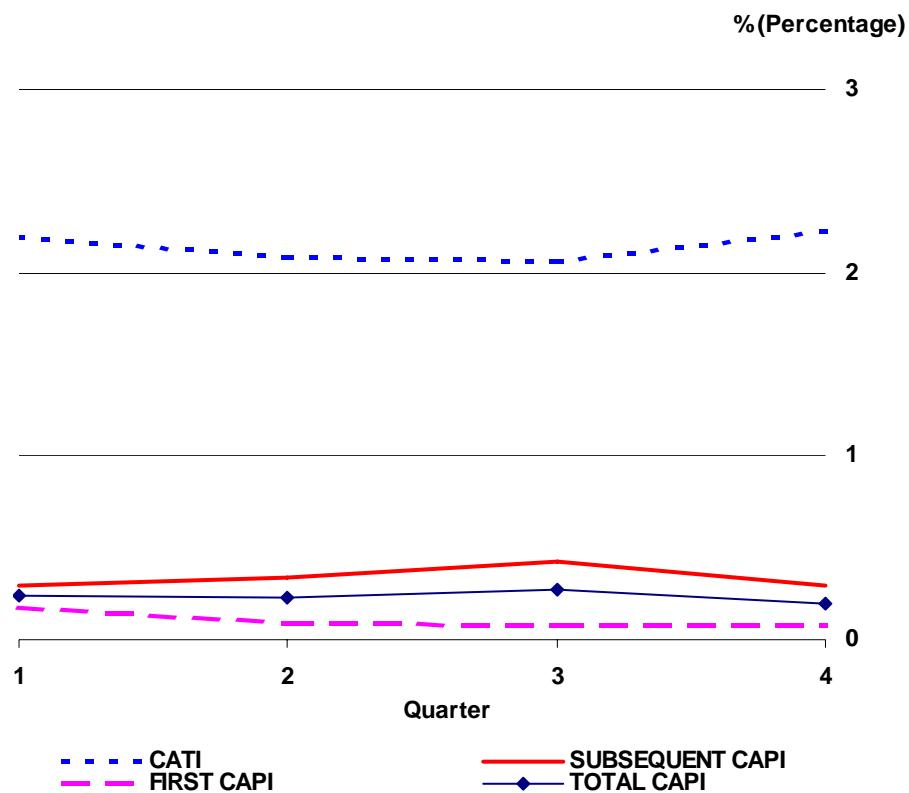

In the case of inaccessibility in CATI, it is attempted to collect information by means of a personal interview, so long as this is feasible. Otherwise the dwelling is finally considered inaccessible and revisited the following quarter, but assigning it to CAPI.

Graphs 1 and 2 represent the percentages of unavailable dwellings, in the four quarters of the year, in the selected dwellings assigned to CATI and in those assigned to CAPI. The percentages are calculated in relation to the corresponding number of selected dwellings. In the case of the latter collection method, a distinction is made between the first and successive interviews.

**Graph 1** shows, at first sight, that the percentages of unavailable dwellings are somewhat higher with CATI than with CAPI, which seems logical since, in CAPI, inaccessibility is due, as has already been mentioned, to adverse climatological conditions or to the absence of adequate roads to access the same, circumstances which, normally, do not involve a high number of cases.

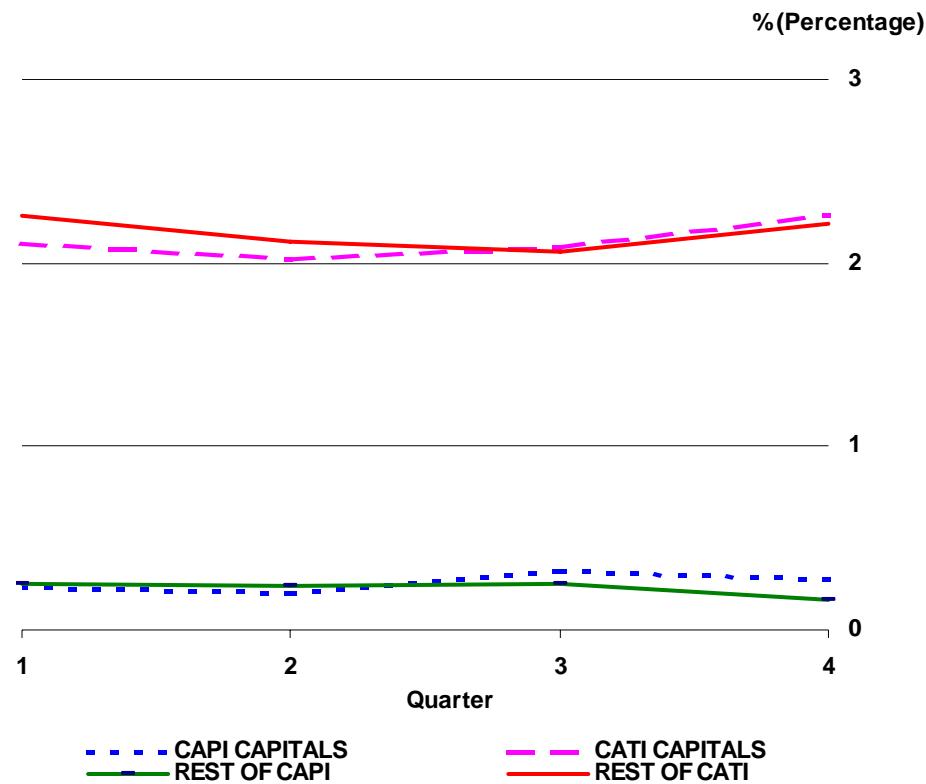

In the case of CAPI, a distinction is made between first and successive interviews, it being possible to observe that percentages are somewhat smaller in the first interview.

## Graph 1 Unavailable dwellings

The percentages of unavailable dwellings according to the type of municipality (capitals or other) appear represented in **graph 2**, where it can be seen, both in CAPI and in CATI, there are no significant differences.

## Graph 2 Unavailable dwellings

### 3.2 Failure to update the framework

A dwelling is defined as *not surveyable* in the APS when, at the time of the interview, it is empty, it is a seasonal dwelling, it is intended for other purposes, or it is unlocatable at the address that appears in the selection list. These cases indicate that the framework of the survey is not updated, or contains errors, and these units may be considered as *erroneous inclusions in the framework*.

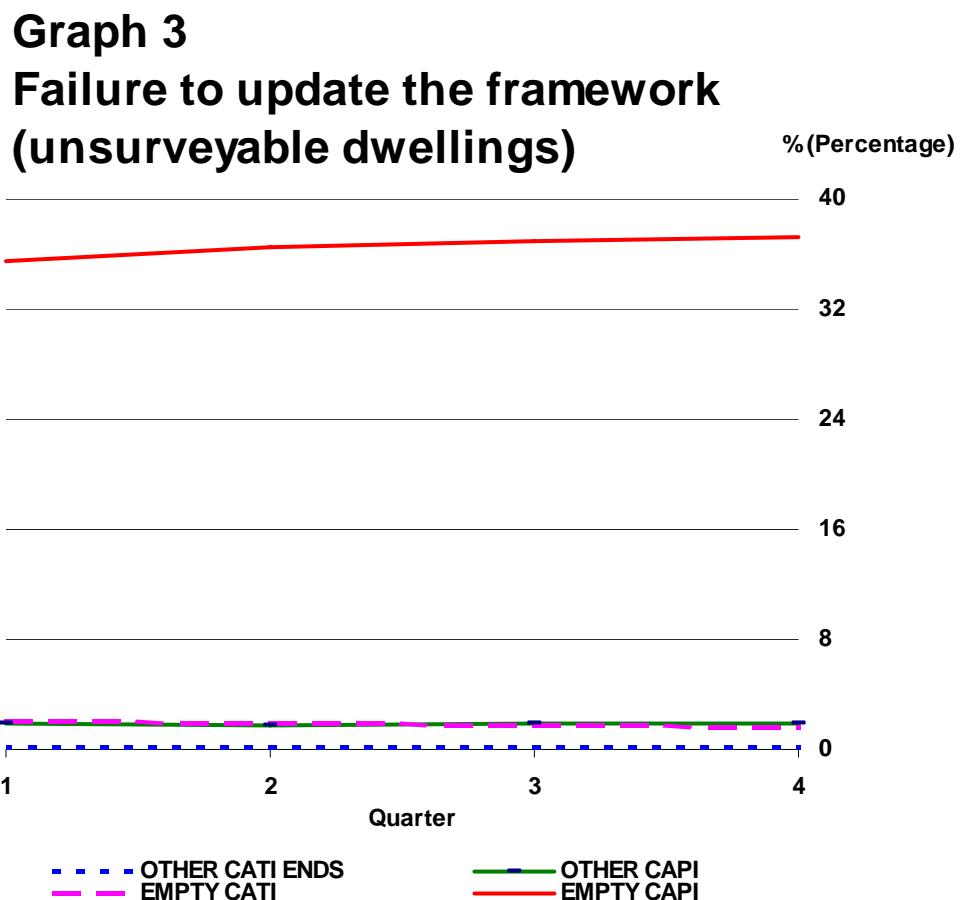

Table F.D.0 in the Annex contains a summary of incidences which have taken place, in the four quarters of the year, in the total number of selected dwellings, in other words, including those assigned to CAPI and in those assigned to CATI. The information is broken down into *first and successive interviews*, on the one hand, and into *capitals and other municipalities* on the other.

The breakdown of incidences in dwellings assigned to the CAPI method can be seen in table F.D.1 in the Annex, where a distinction is made between provincial *capitals* (stratum 1) and other *municipalities* (strata 2 to 9) and between *first and successive interviews*. In this table we can observe that the fact that it is out of date is basically due to the high number of *empty dwellings*, regarding which the number corresponding to those *intended for other purposes* and those *unreachable*, jointly known as *others* in **graph 3** shown below, is

practically insignificant. The total percentage of empty dwellings in CAPI increases slightly between the first and the fourth quarter, fluctuating between 35.6 and 37.3 percent.

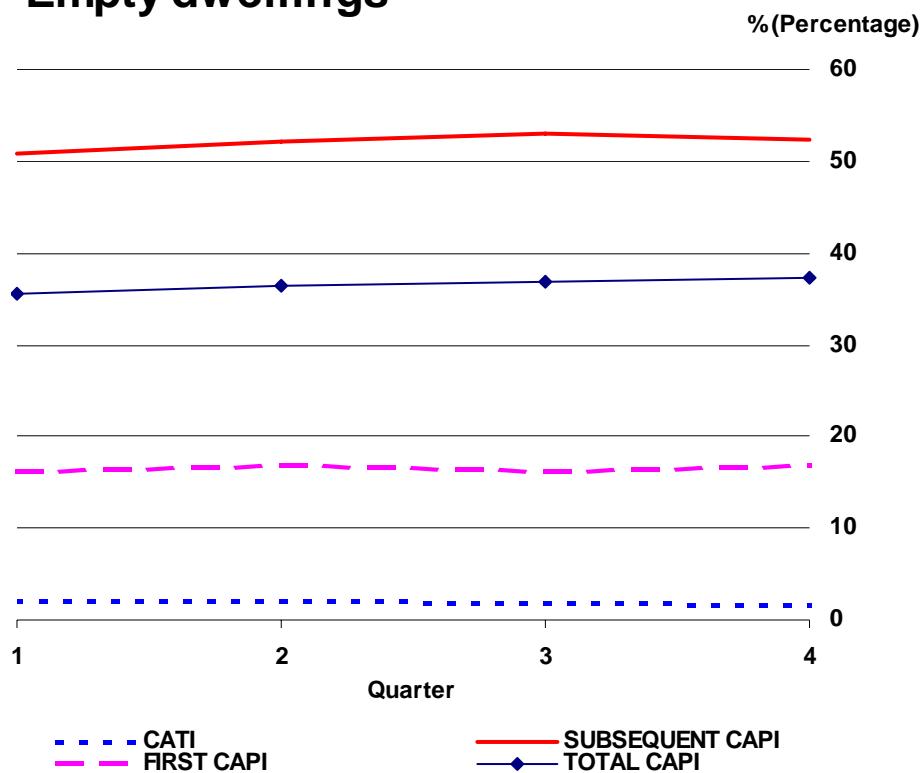

Conversely, table F.D.2 in the Annex shows the incidences of dwellings assigned to the CATI method, and it can also be seen that the failure to update the framework is primarily due to empty dwellings, which are equally insignificant regarding those *intended for other purposes* as a whole (in CATI there are no unreachable dwellings). We can observe that the percentage of empty dwellings did not undergo any large variations, and that they decreased slightly and gradually between the first quarter (2 percent) and the fourth quarter (1.6 percent). This table only draws a distinction between capitals and other municipalities, since all dwellings assigned to CATI are in subsequent interviews.

**Graph 3** shows the percentages of unsurveyable dwellings in CATI and in CAPI throughout the year; we can observe the large difference between percentages of empty dwellings in CAPI and in CATI. This difference may be explained by the fact that for the majority of empty dwellings, there is no telephone number, therefore once they have been detected in the first interview, they must remain assigned to CAPI rather than passing to CATI.

Conversely, empty dwellings are visited (or contacted by telephone where possible) all quarters as if they had come to be inhabited; therefore the highest percentages for empty dwellings in successive interviews in CAPI (please see table F.D.1), fluctuating between 51 and 53 percent of selected dwellings, whereas in the first interview they fluctuate around 16 percent, as can be verified in **graph 4**.

### Graph 4 Failure to update the framework Empty dwellings

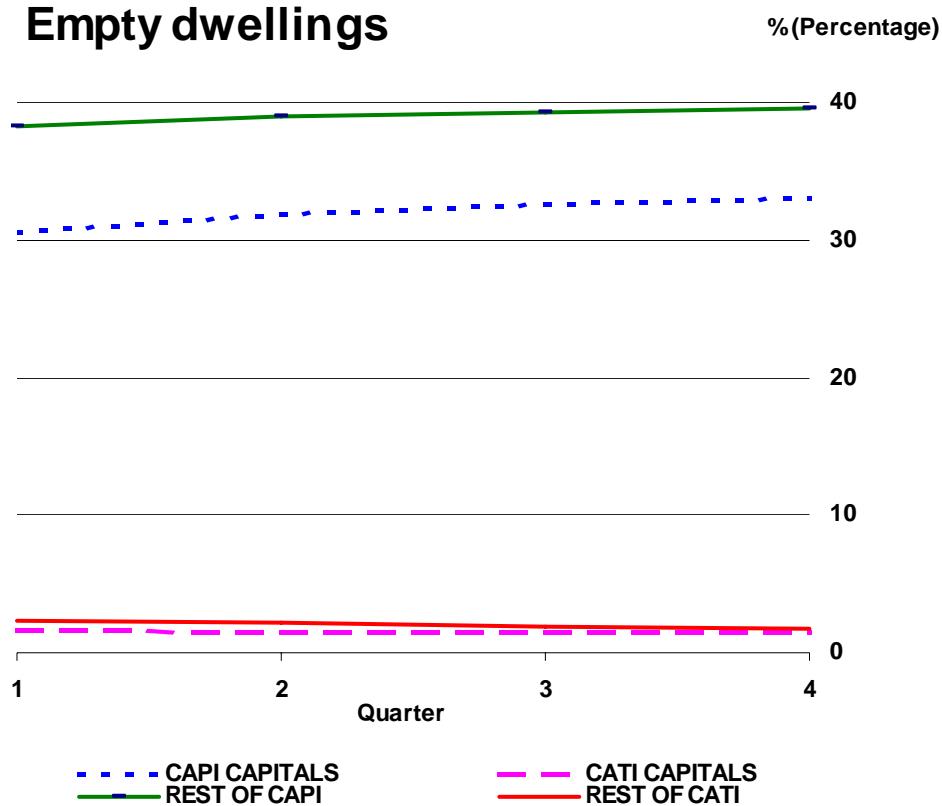

On the other hand, **graph 5** shows empty dwellings in CATI and in CAPI, differentiating in both cases between capitals and other municipalities. It can be seen that both in CATI and in CAPI, the percentages of empty dwellings is higher in other municipalities than in capitals, although in CAPI the differences are somewhat greater than in CATI, where they are minimal.

In addition to the periodic updating of likelihood of the section sample, and in order to keep the sample updated, in each quarter in the survey the framework of dwellings of the sixth part of the sample sections is updated, by established rotation shifts and previously commented upon.

This update consists of going through the section in order to register newly-constructed buildings and dwellings, visit empty dwellings and commercial

premises, in case any of them have become inhabited dwellings, and verify the section's limits.

### Graph 5 Failure to update the framework Empty dwellings

Within the quality evaluation programme, in order to detect mistakes made in the process of updating the sample sections, a sample of 200 sections per year has been selected to go through it a second time. Of these, it has only been possible to investigate 174 due to different incidences occurring in the organisation of the fieldwork.

*Unsurveyable* dwellings, according to the original interview (O.I.), and *surveyable* ones according to the repeat interview (R.I.) are actually *omitted* in the framework, and therefore they are unlikely to form part of the sample.

The results by stratum, expressed as a percentage of the surveyable dwellings from the sections selected for assessment are collected in **chart 2**.

We can observe that the percentage of dwellings omitted in the framework for the stratum total is very small, 1.28 percent, which makes it possible to state that updates are generally carried out fairly well.

## 2. Omissions of dwellings in the framework

Stratum	Sections updated in the R.I.	Dwellings surveyable by O.I.	Unsurveyable dwellings by O.I. and surveyable according to R.I. (omissions)		Percentage
			Total		
1	62	36,850	516	1.40	
2	8	4,869	63	1.29	
3	3	1428	14	0.98	
4	7	4,150	30	0.72	
5	23	13,916	168	1.21	
6	15	10,902	42	0.39	
7	22	13,627	256	1.88	
8	18	9,127	154	1.69	
9	16	4,872	35	0.72	
<b>Total</b>	<b>174</b>	<b>99,741</b>	<b>1,278</b>	<b>1.28</b>	

### 3.3 Non-response

Non-response in a dwelling belonging to the group being studied may be due to the absence of its occupants, or their refusal to cooperate in the survey.

The percentages of these two types of incidence are shown in tables F.D.1 and F.D. 2 in the Annex, these being calculated with regard to the total for surveyable dwellings, as can be seen. **Graph 6** similarly shows the evolution throughout the year of the two components of non-response, with a distinction being made between CATI and CAPI.

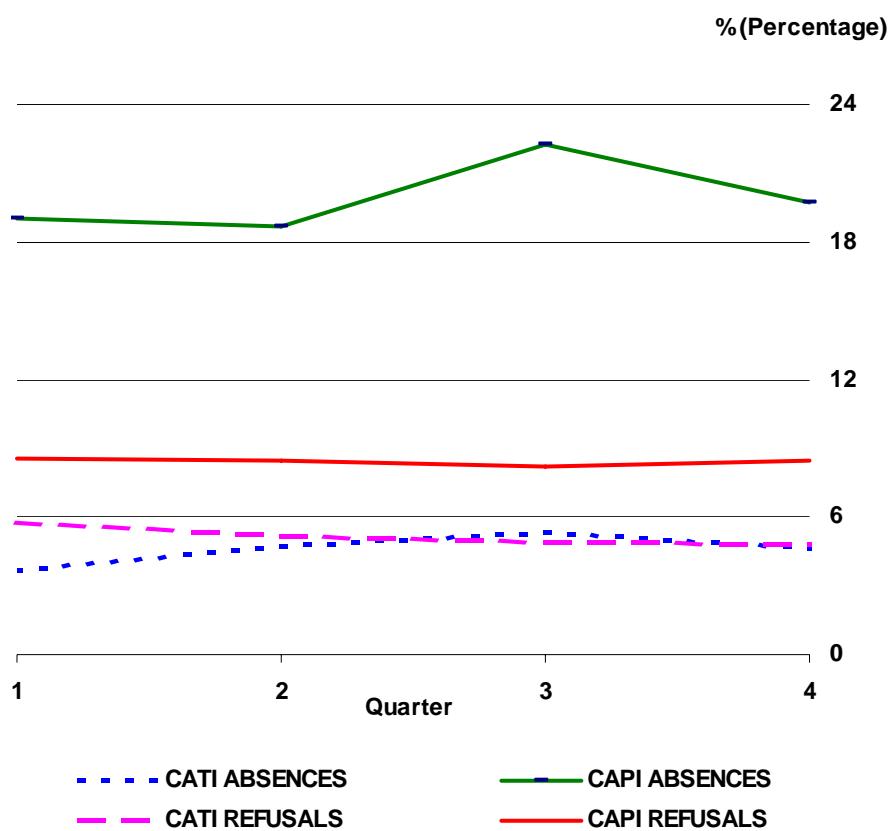

With CAPI we can observe that the percentages of absences are somewhat higher than for refusals, since whereas the former stand, on average, at around 20 percent, the latter stand at around 8.5 percent. With CATI, on the other hand, the percentages of refusals and absences are more similar, with those corresponding to refusals being higher, except in the third quarter, in which absences surpass refusals, a normally common set of circumstances due to the fact that the aforementioned quarter coincides with the most common holiday period for the population. We can also observe in CAPI that it is in the third quarter that the maximum percentage of absences is reached.

If we compare the percentages of absences in CATI and in CAPI, we can see that they are somewhat higher with the latter collection method. This seems reasonable if we take into account the fact that it is easier to contact a resident in the dwelling, during the day, by telephone rather than by a personal visit, particularly in dwellings in which all residents work away from home.

Regarding refusals, we can observe that the percentages are likewise higher in CAPI than in CATI, although in this case the differences are smaller.

## Graph 6

### Non-response

#### 3.3.1. REFUSALS

Refusal occurs when all persons aged 16 years old or over, who are resident in the dwelling, refuse to cooperate with the survey.

If the refusal occurs in the first quarter of cooperation, the dwelling is randomly replaced by a reserve from the same section, until a group is found that will cooperate or will be absent or inaccessible. When refusal occurs in the second or subsequent quarters of cooperation, no replacement is made and an imputation is carried out with the data for the previous quarter, with the dwellings revisited during the remaining quarters during which they remain in the survey (up to six) in case they change their stance or in case of changes to the human group. This imputation is only carried out the first time there is a refusal; if this persists into the following quarters, it entails a sample loss.

Therefore, refusals in successive interviews are not, by and large, first-time refusals, but rather *ongoing* refusals from previous interviews.

In tables F.D.1 and F.D.2 in the Annex and in graph 6, we can see that the percentage of refusals remains fairly stable throughout the year, both in CATI and in CAPI, its average percentage standing at approximately 5 percent of surveyable dwellings in CATI and around 8.5 percent in CAPI.

When refusal occurs for *the first time*, a *questionnaire of refusals* is completed in order to collect data for assessing possible biases, which may arise from non-response. This data is: sex, age and relationship with the dwelling reference person, who refuses to cooperate in the survey, and age, sex, nationality, educational level, relation to the activity, occupation and branch of activity of the reference person.

In case the human group refuses to provide this information (*direct information*), information taken from previous interviews is queried (where there was previous cooperation) or, lastly, the Municipal Register of Inhabitants. **Chart 3** shows the origin of information for refusal questionnaires in the four quarters, for the total of these, and making a distinction between the CATI and CAPI.

We can observe that, in the case of CAPI, the majority (76 percent on average) of data from refusal questionnaires is obtained via *direct information*, whereas in CATI it is the *information taken from previous interviews* that constitutes the main source of information, with 94 percent of data being obtained in this way.

The fact that in CATI, the majority of the information is obtained from previous interview data makes sense, since this collection is only used in successive interviews, once the dwellings have already cooperated, generally, on at least one occasion.

### **3. Origin of the information of the questionnaires of the refusals for the first time**

Origin	Quarter								Average
	First		Second		Third		Fourth		
Total	No.	%	No.	%	No.	%	No.	%	Average
Refusals for the first time	2,606	100.0	2,400	100.0	2,326	100.0	2,282	100.0	2,403.5
- Municipal Register	155	6.0	153	6.4	203	8.7	160	7.0	7.0
- Information from previous interviews	1,408	54.0	1,266	52.8	1,150	49.4	1,105	48.4	51.2
- Direct information	1,043	40.0	981	40.9	973	41.8	1,017	44.6	41.8
<b>CATI</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	
Refusals for the first time	1,386	100.0	1,183	100.0	1,122	100.0	1,040	100.0	1,182.8
- Municipal Register	8	0.6	8	0.7	14	1.3	9	0.9	0.8
- Information from previous interviews	1,258	91.8	1,125	95.1	1,046	93.2	981	94.3	93.6
- Direct information	119	8.6	50	4.2	62	5.5	50	4.8	5.8
<b>CAPI</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	<b>No.</b>	<b>%</b>	
Refusals for the first time	1,220	100.0	1,217	100.0	1,204	100.0	1,242	100.0	1,220.8
- Municipal Register	147	12.1	145	11.9	189	15.7	151	12.2	13.0
- Information from previous interviews	149	12.2	141	11.6	104	8.6	124	10.0	10.6
- Direct information	924	75.7	931	76.5	911	75.7	967	77.9	76.4

If we correlate the average quarterly number of first-time refusals in chart 3 with the average quarterly number of total refusals (obtained by adding the refusals in charts F.D.1 and F.D.2 in the Annex), we obtain the average quarterly number of *first-time refusals* standing at 58 percent of the total number of refusals.

As previously mentioned, the dwellings composing the sample remain in it for six consecutive quarters, and a sixth of them is renewed each quarter in accordance with established rotation shifts.

**Chart 4** shows the distribution of the total for *first-time refusals* according to the number of the interview in which they occurred, in accordance with the rotation shift corresponding to the dwelling (theoretical interview). The reason for assigning the interview number depending on the rotation shift of the dwelling, rather than the number of cooperation's of the human group, stems from the fact that, in this way, it is possible to correlate the number of refusals with the total number of surveyable dwellings for each interview, likewise shown in this chart, and thus percentages of more representative refusals may be obtained.

Analysing the data by interview number, we observe that the highest percentages of first-time refusals are obtained in the first interview, reaching on average a value in the region of 7.5 percent of surveyable dwellings, with those given in the sixth interview taking second place, which stand on average at around 4.5 percent.

The total number of refusals has also been broken down according to the collection method used: CATI or CAPI. It can be seen that the percentages for first-time refusals are greater in CAPI than in CATI (6.3 percent as compared with 2.5 percent).

If we compare figures for refusals in the first interview for CAPI in chart 4 and in table F.D.1, it can be seen that there are certain differences between these. The data for table F.D.1 corresponds to refusals for dwellings in which, due to rotation shift, it is the first interview, whereas in chart 4, refusals are presented for the first time, including those occurring in dwellings that are both in first interview and successive interviews (if the refusal takes place following one or more previous collaborations or if there has been a change in the human group), and the figures are therefore not comparable.

Some characteristics of the reference person for dwellings that refused for the first time to cooperate in the APS are presented in **tables F.D.3.1 to F.D.3.6**. It can be observed that, in general, the percentage of cases in which it was not possible to obtain data from the refusal questionnaire (*no data recorded*) is high, particularly for the characteristics *relation to the activity* and *educational level*, for which it stands at approximately 60 and 50 percent, respectively. Such high non-response values subtract validity from any conclusions that can be obtained from these tables; nevertheless, the end of table **F.D.3.3** includes the percentage distribution of family dwellings in accordance with the relation to the activity of the reference person, obtained from the APS 2007 (average for the four quarters), and by comparing this distribution, which serves as a reference, with the one for the quarterly average for refusals, it could be said that first-time refusals are concentrated in dwellings where the reference person is in another situation in relationship with the activity, in other words, in that he or she is neither employed nor unemployed.

In the remaining tables it has not been possible to obtain reference distributions, since they are not readily available among the APS information.

## 4. Refusals for the first time according to the number of the interview, by rotation shift

Number of interview by rotation shift	Quarter										
	First					Second					
	Surveyable		Refusals			Surveyable		Refusals			
<b>Total</b>	No.	%	No.	%		No.	%	No.	%		
Refusals for the first time	65,976	100.0	2,606	3.9		66,448	100.0	2,400	3.6

Conversely, **table F.D.3.7** presents the distribution of first-time refusals in accordance with the number of persons in the dwelling. In the final column of this table, it has been possible to include, as in **table F.D.3.3**, the percentage distribution of family dwellings by number of persons obtained from the APS 2007 (average for the four quarters). If we compare this distribution with the one for the quarterly average of refusals, we may reach the conclusion that first-time refusals are concentrated primarily in two-person dwellings and, to a lesser extent, in one-person dwellings. Nevertheless, the high percentage of *no data recorded* decreases the reliability of this conclusion.

## 5. Refusals for the first time according to the reason expressed by the person refusing the interview

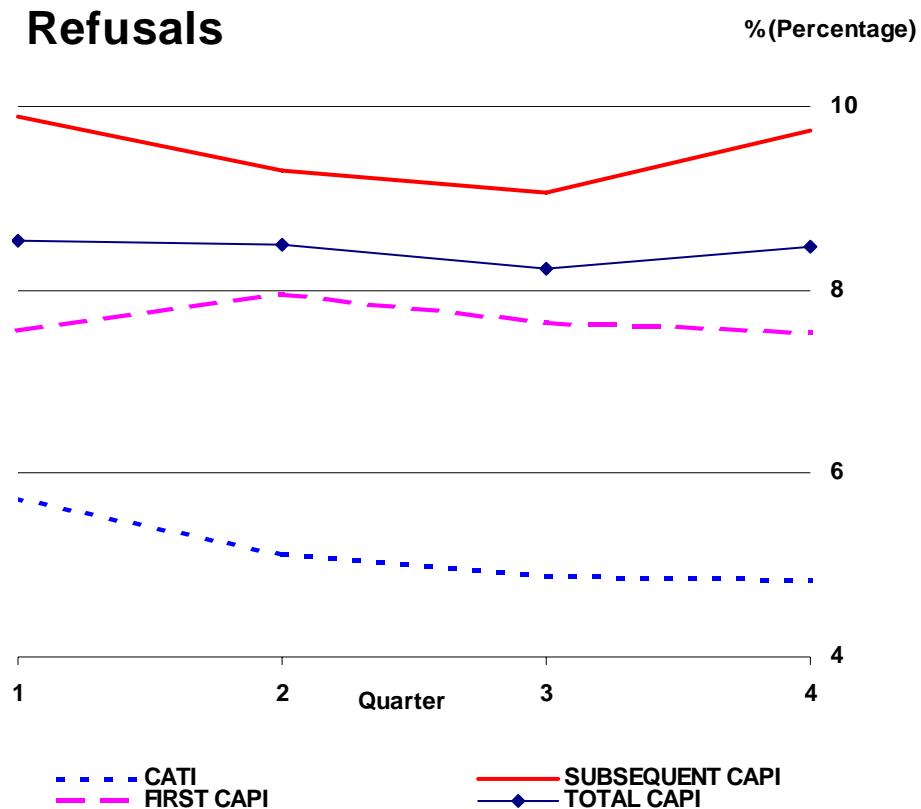

Reason	Quarter								Average
	First		Second		Third		Fourth		
Total	No.	%	No.	%	No.	%	No.	%	Average
Refusals for the first time	2,606	100.0	2,400	100.0	2,326	100.0	2,282	100.0	
-No reason expressed	678	26.0	644	26.8	661	28.4	614	26.9	27.0

-Other	152	12.5	125	10.3	117	9.7	135	10.9	10.8

Lastly, **chart 5** present the distribution of first-time refusals according to the reason expressed by the person refusing the interview, distinguishing between CATI and CAPI. We can observe that in the dwellings assigned to CATI the highest percentage of first-time refusals corresponds, with almost 33 on average, to *lack of interest*; conversely, in dwellings assigned to CAPI the highest percentage corresponds to *no reason given* with 33 percent on average, followed by *death or illness* with 21 percent.

**Graph 7** represents percentages of refusals for CATI and for CAPI in the four quarters, with a distinction being made for the latter method between the first and successive interviews.

## Graph 7

### Non-response Refusals

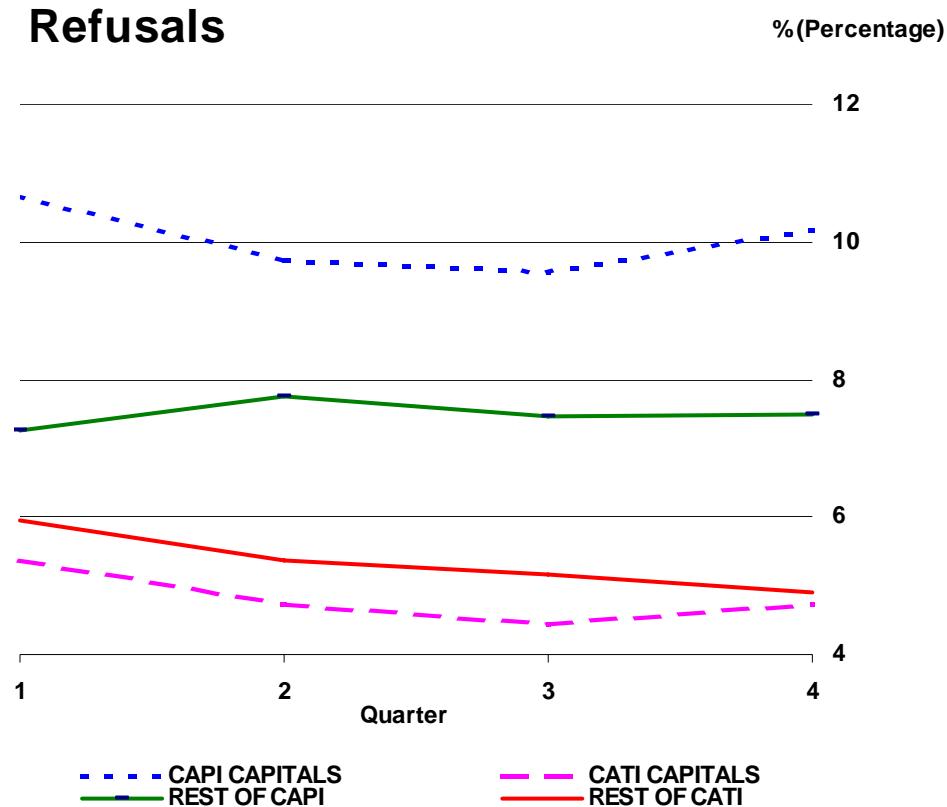

Firstly, please note that the percentages of refusals are somewhat higher in CAPI than in CATI, as we have already mentioned. Secondly, and on the subject of CAPI, we can see that refusals are relatively more numerous in successive interviews than in the first one. This is due to the fact that, as with empty dwellings, refusals are revisited in the remaining cooperation quarters in case there are changes, either in the attitude of the human group with regard to the survey, or the human group itself, therefore refusals in successive interviews are predominantly refusals continuing from previous quarters.

Lastly, we can observe that, whereas in CATI the percentage of refusals has decreased slowly but steadily since the first quarter, in CAPI it should be noted that the total percentage remains practically constant, with a slight decrease in the third quarter.

The percentages of refusals, depending on the type of municipality represented, for CATI and for CAPI, in **graph 8**. It can be seen that in CATI the percentages are slightly higher in other municipalities than in capitals. In CAPI, on the other hand, the opposite is true, in other words, the percentages of refusals are greater in capitals than in other municipalities, with the differences being greater than in CATI in this case.

**Graph 8**  
**Non-response**  
**Refusals**

### 3.3.2. ABSENCES

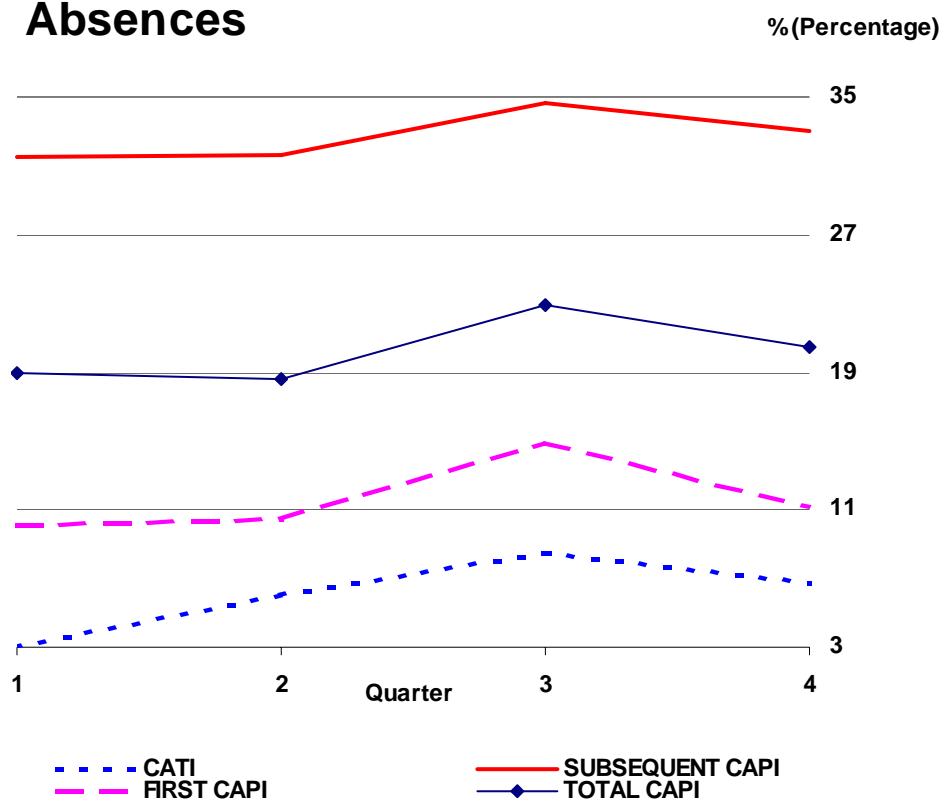

Absence occurs when no one in the occupying group is located at the dwelling in successive visits made to it by the interviewer, during the time it remains in the section.

In the case of temporary absence of the occupants of the dwelling, the interviewer repeats visits or phone calls until the information is obtained, if at all possible. Otherwise they are considered to be permanently absent, and fresh attempts are made to contact them the following quarter.

**Graph 9** represents percentages of refusals for CATI and for CAPI in the four quarters, with a distinction being made for the latter method between the first and successive interviews.

Firstly, please note that the percentages of Absences are somewhat higher in CAPI than in CATI, as we have already mentioned. Secondly, and with reference to CAPI, we can see that absences are somewhat more numerous, in relative terms, in successive interviews than in the first one. This is due, firstly, to the fact that, as with refusals, there are absences continuing from one quarter to the next and, secondly, to the fact that the number of surveyable dwellings is much lower, as compared with that for those selected, in successive interviews than in the first.

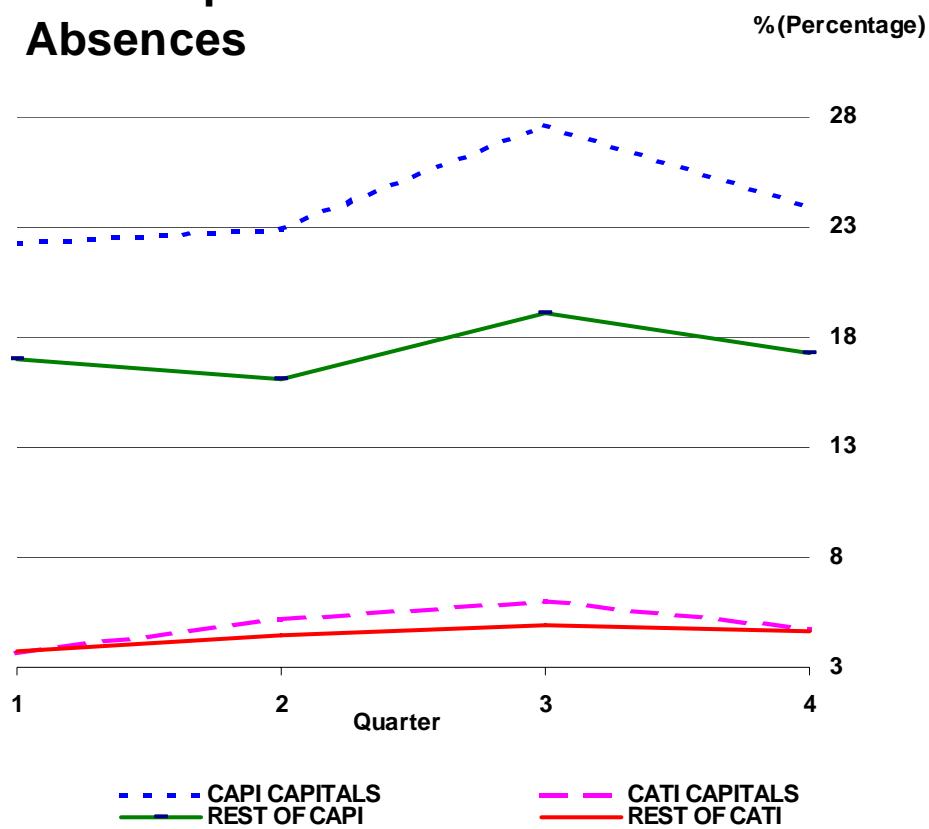

### Graph 9 Non-response Absences

Lastly, we can observe that, whereas in CATI the percentage of absences has increased gradually up until the third quarter, and then decreased in the fourth quarter, in CAPI it should be noted that there is stability in the first two quarters, a considerable increase in the third quarter, and another decrease in the fourth quarter.

The percentages of absences, depending on the type of municipality represented, for CATI and for CAPI, in **graph 10**. It can be seen that in CATI the percentages are slightly higher in provincial capitals, but with very slight differences. In CAPI the performance is the same, in other words, the percentages of absences are greater in capitals than in other municipalities, but with greater differences in this case than in CATI.

**Graph 10**  
**Non-response**  
**Absences**

### 3.4 Incidents In the sample, by Autonomous Community

Charts 6.1.1 to 6.4.2 show the incidences registered in dwellings selected for the four quarters of the years, by Autonomous Community and according to the collection method used. The percentages of surveyed dwellings, refusals and absences have been calculated with regard to the total for surveyable dwellings, instead of regarding the total number of selected dwellings.

Considering the average values of the four quarters, contained in tables 6.5.1 and 6.5.2, in **the dwellings assigned to CAPI** (see **table 6.5.1**) we can see, firstly, that the percentages of unavailable dwellings are very small. In terms of the failure to update the framework, of particular note is Comunidad de Madrid, with 24 percent, the Community with the lowest average quarterly percentage for unsurveyable dwellings, whereas at the other extreme, Islas Baleares stood out with an average percentage for unsurveyable dwellings of 47 percent. These high percentages of unsurveyable dwellings are due, as already mentioned, to the fact that empty dwellings are visited every quarter, as if they had come to be inhabited.

If we then study non-response, including refusals plus absences, we can see that País Vasco is the Community with the highest quarterly average, standing at almost 46 percent. The lowest non-response corresponds to Cataluña, whose quarterly average is 20.6 percent.

If we break down non-response in its components, we can see that the highest annual average percentage of refusals corresponds to País Vasco, with 17 percent, followed by Ceuta, whose percentage of refusals stands at around 14 percent. Among the Communities with fewest refusals, Cantabria, whose quarterly average is below 1 percent, is of particular note.

In terms of absences, Islas Baleares, with an average of 34 percent, is the Community with the highest percentage. At the other extreme is Cataluña, with a value of 9.4 percent, the Community with the lowest percentage.

As regards **dwellings that were assigned to CATI**, and likewise considering the average values for the four quarters (please see **table 6.5.2**), we can observe that the percentages of unavailable dwellings are greater than in CAPI, with Ceuta reaching the highest value, at around 3.7 percent. This fact may be explained by the different meaning of *inaccessible dwelling* in CATI and in CAPI, as already mentioned in sections 3 and 3.1. With regard to unsurveyable dwellings, Asturias is of particular note, with 0.7 percent, as the Community with the lowest average quarterly percentage. At the opposite end of the spectrum, Comunidad Valenciana stands out with 4.3 percent.

If we study non-response, we can see that País Vasco is the Community with the highest quarterly average, standing at 16 percent. The lowest non-response corresponds to Cataluña, whose quarterly average is 7 percent.

If we now analyse non-response component, we can see that with regard to refusals, of particular note is País Vasco, with 11.4 percent. Among the Communities with fewest refusals, Canarias, whose quarterly average is below 3 percent, is of particular note.

In terms of absences, Comunidad de Madrid, with an average of 8 percent, is the Community with the highest percentage. At the other extreme is Cantabria, with a value of less than 3 percent, the Community with the lowest relative number of absences.

## 6.1.1 Incidences in the sample, by Autonomous Community, as a percentage (CAPI)

1st quarter

Autonomous Communities	Selected dwellings				Incidences in surveyable dwellings			
	Not interviewed							
	Total	Unavailable	Surveyable	Total	Surveyable	Refusals	Absences

## 4. Assessment survey

The quality assessment survey of the APS, implemented on an experimental basis in 1970, has a two-fold objective:

- To monitor the work of the interviewers who are involved in the APS.
- To assess the quality of the results.

To this end, we have followed a mathematical model compiled by the Census Office of the United States, due to Hansen, Hurwitz and Bershad, based on the *repeated interview*. The operating procedure, very simple, consists of repeating the interviews in a sample of the dwellings selected for the original survey. Subsequently, the data obtained on both occasions is compared, for the purpose of studying the inconsistencies, and quantifying the errors, through the application of different quality indices. The model of Hansen, Hurwitz and Bershad assumes that, in the second interview, or *repeated interview*, we obtain the true values of the characteristics being studied. Although in practice it is difficult to prove whether or not this objective has been reached, the data from the repeated interview, obtained with more means and better-prepared interviewers, is assumed to be of a superior quality than the primitive data, and will enable basing on it all of the calculations of errors and biases.

The comparison of the results obtained from the original interview (O.I.) with those obtained in the repeated interview (R.I.) allows for evaluating two large types of errors other than sampling errors that affect the quality of the results:

- a) Coverage errors**, produced by the erroneous omission or inclusion of units in the original survey.
- b) Content errors**, which affect the characteristics studied of the surveyable persons.

The fieldwork is carried out by specialised interviewers who conduct the repeated interview at most fifteen days after the original interview, with the data from both interviews referring to the same period of time.

As is well-known, in the APS the information collection method is different according to whether the dwellings are in a first or successive interviews, with CAPI used in dwellings that are in the first interview and primarily CATI in dwellings that are in the second or subsequent interviews.

Due to the fact that there has been a desire to use the same collection method in the assessment questionnaire as that used in the APS, it was decided to use a CAPI system in the repeat interview, foregoing the CATI system due to its greater implementation complexity. Taking into account this set of circumstances, the sample of sections to be investigated in the assessment survey is selected from among the APS sections in the first interview, and therefore the results of this interview will be applicable to dwellings in the first interview. Nevertheless, it is to be expected that the behaviour of dwellings in the second and successive interviews do not show large differences as compared with those in the first.

The assessment survey was once again quarterly, in other words, each quarter a sample of sections to investigate is selected. With each quarterly sample, the aim is to inspect work carried out in all Autonomous Communities, except Ceuta y Melilla, investigating, wherever possible, at least a section of each province.

For quarterly selection of the sample, four zones have been created taking all the Autonomous Communities, except Ceuta y Melilla, grouping several Communities into each, such that each Community is included in one, and only one, of these zones. In order to complete up to thirteen (the number of weeks in each quarter), previous zones have been repeated twice, one of them more than once, in other words, one zone is repeated three times.

Lastly, a zone is assigned by means of a random procedure to each week in the quarter, with visits each week to the sections in the provinces of the Autonomous Communities of the zone corresponding to this.

Using this method between 140 and 150 sections are selected each quarter. In these sections the interview is repeated in half of EO holder dwellings, with even- or odd-numbered dwellings selected at random, the number of investigated dwellings thereby standing at between 1,400 and 1,500, representing approximately 12 percent of dwellings from the first APS interview (2 percent of the total APS sample).

In the repeat interview a slightly reduced questionnaire is used (in other words, with a few less questions) as compared with the short APS questionnaire (the one used in interviews 1 to 5).

Despite the quarterly nature of the assessment survey, the results are to be given for the whole year, since, being independent quarterly samples, it is possible to group the data.

**Chart 7** deals with the distribution of incidences in dwellings selected for the assessment survey (R.I.) sample.

## 7. Incidences in the sample of R.I.

Selected dwellings	No.	%
Total	5,198	100.00
Unavailable	9	0.17
Unsurveyable	1,041	20.03
Surveyable	4,148	79.80
- Surveyed	2,801	53.89
- Non-response	1,347	25.91

In order to compare non-response (refusals+absences) in R.I. and in O.I., **chart 8** presents its percent distributions in both interviews. O.I. data have been obtained by calculating the average for figures corresponding to CAPI from the first interview in the four quarters of the year. It can be observed that the percentage of non-response is much greater in R.I. than in O.I. (32.5 percent as

compared with almost 19 percent), as is usual, with the aforementioned difference due mainly to absences, which have the greatest incidence in non-response. The difference in percentage of absences between O.I. and R.I. is twelve points. Regarding this fact, it is appropriate to emphasize that the R.I. agents conduct their interviews with greater time limitations, given that as they do not reside in the province, they spend less time in the section.

## 8. Percentage distribution of surveyable dwellings in O.I. and in R.I.

Dwellings	O.I.	R.I.
Surveyable	100.00	100.00
-Surveyed	81.15	67.53
-Non-response	18.85	32.47
-Refusals	7.68	9.31
-Absences	11.17	23.17

**Table 9** includes the coincidences and discrepancies in terms of the coverage of dwellings, between O.I. and R.I., in absolute and percent values. From the analysis thereof, it may be concluded that there is a high degree of agreement between both interviews, which is reflected in the gross difference (error percentage indicator), with a value of 0.54 percent.

## 9. Errors in coverage of dwellings

	No.	Percentage
Surveyable/unsurveyable dwellings in O.I. and R.I.	5,189	100.00
Surveyable in O.I. and in R.I.	4,147	79.92
Surveyable in O.I., but not in R.I. (1)	27	0.52
Surveyable in R.I., but not in O.I. (2)	1	0.02
Unsurveyable in both O.I. and R.I.	1,014	19.54
Net difference (1) - (2)	26	0.50
Gross difference (1) + (2)	28	0.54

In the dwellings surveyed in R.I., it is generally not possible to use all of the information to assess the content errors, given that some of them have not been surveyed in O.I., due to the different causes included in **table 10**.

The questionnaires that are processed electronically, and which allow for carrying out the analysis of the errors of coverage of persons and of the content

errors in the different characteristics of the survey, are only those corresponding to the dwellings that have been interviewed in both the R.I. and the O.I.

## **10. Incidences in O.I. of the dwellings that were surveyed only in R.I.**

Dwellings in R.I.	First semester	
	Total	Percentage
Selected	5,198	100.00
Surveyed in R.I. and O.I.	2,796	53.79
Surveyed only in R.I.	5	0.10
-Refusals in O.I.	0	0.00
-Absent in O.I.	4	0.08
-Unavailable in O.I.	0	0.00
-Unsurveyable in O.I.	1	0.02

Moving on, the INE is concerned about obtaining data from the best possible source of information. Thus, in the APS, data on persons inhabiting the dwelling is requested from the reference person, and in any case, from an adult residing there, with no information obtained in those dwellings, which do not comply with these requirements.

**Table 11** presents the data regarding the identity of the informant, obtained in the dwellings in which the two interviews were conducted. In approximately 69 percent of O.I. dwellings, the data was obtained from the reference person, whereas in R.I. dwellings, this percentage stands at 62 percent. The information was provided by the same person in the two interviews in nearly 75% of the dwellings.

The fact that the number of interviewed dwellings in R.I. and in O.I. that appears in tables 10 and 11 does not coincide in general, is due to the use of different sources for obtaining it. Table 10 is obtained from summarising the report files collected in the field, whereas the data in table 11 is obtained once the R.I. and the O.I. questionnaires have been electronically processed.

## **11. Identity of the informant in O.I. and in R.I.**

---

Dwellings interviewed

<u>in O.I. and in R.I.</u>	<u>No.</u>	<u>%</u>
Total	2,758	100.0

### **Informant in O.I.**

-Reference person	1,891	68.6
-Another person	867	31.4

### **Informant in R.I.**

-Reference person	1,699	61.6
-Another person	1,059	38.4

### **The same informant**

<b><u>in O.I. and in R.I.</u></b>	2,055	74.5
-----------------------------------	-------	------

## 5. Coverage of persons

Those persons who reside in dwellings in which it has been possible to conduct an interview, both for the original survey and for the evaluation survey, are classified into one of the three following classes:

- Comparable persons
- Omitted persons
- Persons erroneously included

Comparable persons are those persons that both the O.I. interviewer and the R.I. interviewer have considered surveyable. Therefore, we have information for these persons in O.I. and in R.I..

Omitted persons are those persons whose data has been collected by the R.I. interviewer, on considering them surveyable, but for whom information does not exist in the O.I..

Persons erroneously included are those persons who appear in the questionnaire of the original survey and who the R.I. interviewer has not included in the evaluation survey, on not considering them surveyable.

Both the omissions and the erroneous inclusions are considered errors in the coverage of persons, based on the hypothesis that the information from the repeat interview is of a better quality than that from the original interview.

The evaluation of the coverage of persons is based solely on the occupants of the *surveyable* dwellings in which the O.I. and the R.I. have been conducted, chart 12 shows that such coverage is good.

### 12. Coverage of persons aged 16 years old and over

Persons	No.	%
Interviewed in R.I.	6,363	100.00
-Comparable	6,312	99.20
-Omitidas en O.I.(1)	51	0.80
Interviewed in O.I.	6,334	99.54
-Comparable	6,312	99.20
-Erroneously included in O.I. (2)	22	0.35
Net difference (2)-(1)	-29	-0.46
Gross difference (2)+(1)	73	1.15

This chart presents the net and gross differences, interpreting the first as an indicator of the distortion, and the second as an indicator of the total errors made.

From the analysis of the data, we conclude that the distortion is small, as it stands, in absolute values, at 0.46%, whereas the gross difference stands at 1.15%, a figure similar to those from previous years.

Notwithstanding the small number of persons omitted and erroneously included, tables C.P.1 and C.P.6 of the Annex show the distributions of the same by age, sex, marital status and relationship with economic activity.

# 6. Content errors

## 6.1 Presentation of results

Content errors are analysed from the information supplied, in the two interviews, by the persons classified as comparable. The O.I. and R.I. questionnaires for these persons are compared using computer procedures, determining to what extent the two data series differ. To facilitate the analysis, two types of table are compiled: coincidence tables and quality indicator tables.

For a characteristic C with K modalities, the coincidence table responds to the following general format:

R.I.	O.I..	Total persons	M <sub>1</sub>	M <sub>2</sub>	...	M <sub>j</sub>	...	M <sub>k</sub>
Total Persons	n	n <sub>.1</sub>	n <sub>.2</sub>	...	n <sub>.j</sub>	...	n <sub>.k</sub>	
M <sub>1</sub>	n <sub>1.</sub>	n <sub>11</sub>	n <sub>12</sub>	...	n <sub>1j</sub>	...	n <sub>1k</sub>	
M <sub>2</sub>	n <sub>2.</sub>	n <sub>21</sub>	n <sub>22</sub>	...	n <sub>2j</sub>	...	n <sub>2k</sub>	
...	...	...	...	...	...	...	...	
...	...	...	...	...	...	...	...	
...	...	...	...	...	...	...	...	
M <sub>i</sub>	n <sub>i.</sub>	n <sub>i1</sub>	n <sub>i2</sub>	...	n <sub>ij</sub>	...	n <sub>ik</sub>	
...	...	...	...	...	...	...	...	
...	...	...	...	...	...	...	...	
...	...	...	...	...	...	...	...	
m <sub>k</sub>	n <sub>k.</sub>	n <sub>k1</sub>	n <sub>k2</sub>	...	n <sub>kj</sub>	...	n <sub>kk</sub>	

n<sub>ij</sub> represents the number of persons classified in modality M<sub>i</sub> according to the R.I., which in O.I. had been classified in modality M<sub>j</sub>.

The main diagonal includes the number of persons classified in the same position in both interviews in each modality.

These tables allow for studying the transfers of population between modalities, due to content errors.

From the coincidence table, we can extract, for each modality M<sub>i</sub> of characteristic C, a dual-entry table as shown below:

R.I.	O.I.	With Modality $M_i$	Without Modality $M_i$	Total
With Modality $M_i$		a	b	b
Without Modality $M_i$		c	d	c + d
TOTAL		c	b + d	n

where:

- n** the total persons classified in both interviews, with regard to the reference characteristic.
- a** the number of persons classified in modality  $M_i$  in both interviews.
- b** the number of persons classified in modality  $M_i$  in R.I. and in a different one in O.I.
- c** the number of persons classified in modality  $M_i$  in R.I. and in a different one in O.I.
- d** the number of persons not classified in  $M_i$  in either of the interviews.

Based on this reduced table, the following quality indicators are defined:

**a) Percentage classified identically**

$$P.I.C.(M_i) = \frac{a}{a+b} \cdot 100$$

Varies from zero to one hundred. This is an indicator of response stability. Its optimum value, one hundred, expresses that all persons belonging, according to R.I., to modality  $M_i$ , are classified in the same way in O.I.

**b) Net change index**

$$I.C.N.(M_i) = \frac{c-b}{a+b} \cdot 100$$

This may be positive ( $c>b$ ) or negative ( $c<b$ ). It measures the response bias of the survey, expressed as a percentage of the number of households belonging to  $M_i$ , according to R.I. Given that, for its calculation, it does not consider the different weighting of the data in each stratum, this index can only be interpreted as an indicator of the bias, and not as an estimator.

**c) Net rate of difference**

$$T.D.N. (M_i) = \frac{c - b}{n} \cdot 100$$

**c) Gross change index**

$$I.C.B. (M_i) = \frac{c + b}{a + b} \cdot 100$$

It may be non-existent or positive. This is an indicator of the variance of response, expressed as a percentage of the number of households belonging to  $M_i$  in the R.I. It serves as a measurement of the errors that have been made in this modality.

**e) Gross rate of difference**

$$T.D.B. (M_i) = \frac{c + b}{n} \cdot 100$$

From the definition of these indicators, we conclude that, if there are no content errors in a modality, the P.I.C. takes on the value of one hundred, and the two indices and the two rates take on the value of zero.

It is also important to note that a small, or non-existent, P.I.C. can co-exist with zero bias. This occurs when errors cancel each other out and  $b=c$ . In turn, the I.C.B. can only take on the value of zero if  $b=c=0$ , that is, if there is no content error.

The **global consistency index** is used to compare the general quality of the different characteristics assessed, which is defined, for a certain characteristic C, as:

$$I.C.G. (C) = \frac{\sum_{i=1}^n n_{ii}}{n} \cdot 100$$

---

## **6.2 Analysis of the characteristics assessed**

We have obtained coincidence tables for the following characteristics (section 4 of the Annex):

**a) For the population aged 16 years old and over**

- Age
- Marital status
- Nationality
- Level of training
- relation with the economic activity

**b) For the economically active population**

- Age and sex
- Marital status
- Level of training
- Professional Status
- Occupation
- Branch of activity

**c) For active person employed**

- Hours worked in the main activity
- Number of hours worked equal or different to usual
- Reason for working week time different to usual
- Time that they have been working in their current job
- Employees by sex and type of contract or labour relationship
- Employees with a temporary contract by Public or Private Sector and duration thereof.

**d) For unemployed persons**

- Sex
- Economic sector
- Time that they have been seeking work

As already mentioned, the fact that quarterly samples are independent enables grouping of data obtained in the four quarters. This, together with the fact that the quarterly samples are small, has led to the conclusion that it was preferable to present data for the entire year, rather than separately for the four quarters, in

order to thus obtain more representative data. Therefore data corresponding to the whole of 2007 is presented in the coincidence tables.

Quality indicator tables (section 5 of the Annex) have only been obtained for the characteristics presenting a reduced breakdown:

**For the comparable population aged 16 years old or over**

- Age
- Marital status
- Nationality
- Level of training
- Relation with the economic activity

**b) For the economically active population**

- Professional Status
- Occupation
- Branch of activity

**c) For active person employed**

- Hours worked in the main activity
- Number of hours worked equal or different to usual.

---

#### 6.2.1 AGE, MARITAL STATUS, NATIONALITY AND LEVEL OF TRAINING

The coincidence tables obtained for these characteristics and the corresponding quality indicators are presented in tables C.1 to C.4 and I.1 to I.4 of the Annex, respectively.

The *age* characteristic presents in all its modalities **very high** percentages identically classified (P.I.C.) as has become commonplace, since in all modalities they exceed 98 percent. Net change indices, bias indicators, are fairly small and largely positive, and with regard to indices of gross change, they remain at equally small values, since they only exceed 3 percent in one modality.

With regard to *marital status*, we can see, as is usual, that the modalities *single*, *married* and *widowed* present percentages identically classified somewhat higher than the modality *separated or divorced*, which has a P.I.C. of 86 percent. For the first three modalities, the net change indices are fairly small, and are somewhat larger, although not excessively so, in the modality *separated or divorced*; in indices of gross change, we can observe something similar, a considerable difference between those corresponding to the first three and the

one for *separated or divorced persons*, in which it reaches a value of 18 percent. It is also appropriate to warn that it is in the modality *separated or divorced* where fewest persons are classified, barely 3.9 percent of the total classified.

In the characteristic *nationality*, the primary modality, into which 96.2 percent of the total is classified (see table C.3 of the Annex), is *Spanish*. This modality presents the highest P.I.C. (99.7 percent) and very small net and gross change indices. The other two modalities are, then, a very small minority, particularly *Spanish and other*, therefore their indicators may not be regarded as very significant.

As regards training level, it should firstly be mentioned that, as of this year, the modality *Training and labour insertion with secondary degree (2nd stage)* has been discontinued both in O.I. and in R.I., due to the low number of persons who, in previous years have been classified therein, these persons having come to be classified in the modality *Higher Education, except Doctorate*.

It should be noted, as borne out in table C.4 of the Annex, the low number of persons classified in the modality *Doctorate* implies that its indicators are in no way significant.

In table I.4 of the Annex, we can see, without taking into account indicators of the modality *Doctorate*, in view of their lack of quantitative importance, that the highest P.I.C. corresponds to the modality *Higher education, except doctorate*, which reaches a value of 90 percent. With reference to the net and gross change indices, we can see that they are not unduly high.

In order to compare general quality of the four characteristics previously analysed, chart 13 presents the global consistency index (G.C.I.) thereof. We can see that it is the characteristic *nationality* which presents the highest G.C.I., followed by *age* and *marital status*, with *level of training* presenting the worst index, with 84.8 percent, a value nonetheless substantially higher than the one corresponding to 2006 (72.6 percent).

### **13. Global consistency indices**

Feature	G.C.I.
Age	99.10
Marital status	98.11
Nationality	99.51
Educational level	84.77

If we look at table C.4 of the Annex, we will see that among the different modalities of the characteristic *level of training*, there are population transfers which, in specific cases, take on significance. Thus, for example, of persons who in R.I. are classified as *illiterate*, there is 36 percent who in O.I. were classified in the modality *Primary education*. Also of significance, although less so, are population transfers between modalities *Secondary education, first stage* and

*Primary education*, since, as we can see, 13 percent of persons who were classified in R.I. in the modality *Secondary education, first stage*, were classified in O.I. in the modality *Primary education*, whereas the 10 percent classified in R.I. in *Primary education* are classified in O.I. in *Secondary education, first stage*. It appears, however, that these transfers are losing significance as compared with previous years.

These discrepancies are primarily due to the frequent changing of study programmes, making it difficult to fit a specific level of studies into the classification used therein and, therefore, complicating its encoding.

Conversely, there is a certain trend whereby persons raise their social status, stating a higher level of studies in R.I. than in O.I., a trend that is bucked in 2007, as can be seen in chart 14.

#### **14. Persons with a different educational level in the two interviews**

---

Educational level	No. of cases
Higher in R.I.	415
Higher in O.I.	544

---

##### **6.2.2. RELATION WITH THE ECONOMIC ACTIVITY**

The results obtained for this characteristic in 2007 are presented in tables C.5 and I.5 for the total population aged 16 years old and over, C.6 for males aged 16 years old and over and C.7 for females aged 16 years old and over.

For the total population aged 16 years old and over, the percentages identically classified for the modalities *employed* and *inactive* stand at over 97 percent, with both modalities furthermore presenting small net and gross change indices.

Of the different submodalities of the modality *inactive* it is *another situation* that presents the worst indicators, these also being the least important one quantitatively, since fewest persons are classified in it.

The modality *unemployed* systematically presents one of the lowest P.I.C.s, reaching a value of 72 percent in 2007, a value slightly higher than in previous years. As regards the distortion, with a negative sign, we can see in table I.5 that it is not very high, whereas the index of gross change reaches a value (45 percent), which may be ranked as moderate.

This modality is traditionally one of the most difficult to collect, since in order to establish the condition of unemployed, it is necessary to respond to an extensive set of questions, which may give rise to discrepancies between the two interviews.

Chart 15 shows the population transfers between the modality *unemployed* and the other two (*employed* and *inactive*), expressed as a percentage of the R.I. total in the former. We can see that those classified as *unemployed* in R.I., barely 4.5 percent were classified as *employed* and 23 percent as *inactive*, most of the latter in the submodality *housework*, in O.I. These figures indicate that these transfers are quantitatively of less significance than those observed in previous years.

## **15. Percentage distribution of persons who are unemployed in R.I., according to their situation in O.I.**

Situation in O.I.	Percentage
Employed persons	4.50
Unemployed persons	72.35
- Seeking first job	10.93
- Have worked previously	61.41
Inactive persons	23.15
- Students	3.22
- Homemakers	14.47
- Other inactive persons	5.47

The global consistency indices for the characteristic *relation to the activity* and its main modalities are presented in chart 16.

## **16. Global consistency indices**

Feature	G.C.I.
Relationship with economic activity	96.51
- Men	97.46
- Women	95.88
Active persons	98.72
- Men	99.03
- Women	98.41
Inactive persons	92.27
- Men	94.48
- Women	91.23

The global consistency index of the *relation to the activity* has been calculated only considering its main modalities (*active* and *inactive*), reaching a value somewhat higher than in previous years.

The global consistency index is greatest in the *active* group than in the *inactive* one, as is usual, undoubtedly due to difficulties arising from classifying persons into groups not mutually exclusive within inactive, such as disabled persons, retired persons and housework.

If we take a look at table C.5 of the Annex, we can see that, within the group of those considered to be *inactive* in both interviews, there are significant population transfers between some of its modalities. Thus, for example, 20 percent of persons classified as *disabled* in R.I. are *retired people* in O.I., whereas of those classified in *another situation* in R.I., 13.6 percent are classified as *housework* in O.I. Nevertheless, it should be pointed out that these transfers, which in themselves are quantitatively insignificant, due to the number of persons classified in R.I. in the aforementioned modalities being rather small, this year they are smaller than in previous years.

---

#### 6.2.3. ECONOMICALLY ACTIVE POPULATION

The economically active population is composed of those persons aged 16 years old or more who have a job in the reference week of the survey and those other who, since they do not have a job, are looking for one or are waiting to start one.

For this group of the following characteristics are studied: *age, sex, marital status, educational level, professional situation, occupation and branch of activity*. Results are presented in tables C.8 to C.14 and in tables I.6 to I.8 (the latter correspond to the last three characteristics) of the Annex.

The global consistency indices for the characteristic can be seen in chart 17.

## 17. Global consistency indices

Feature	G.C.I.
Age	99.62
- Men	99.73
- Women	99.92
Marital status	97.91
- Men	98.38
- Women	97.69
Educational level	83.51
- Men	81.84
- Women	85.98
Professional status	94.43
Occupation	84.30
Branch of activity	91.07

On comparison of the *educational level* and *marital status* indices with these same characteristics for the population aged 16 years old or over (see chart 13) we can see that they are greater for this population than for the active population, particularly in the case of *educational level*. Conversely, the G.C.I. for the characteristic *age* is somewhat larger in the case of the active population.

The global consistency index for the characteristic *professional situation* stands at 94.4 percent. This is influenced by the good quality of the indices in the modality *employees* (see table I.6 from Annex), which includes approximately 81 percent of persons classified by this characteristic. The modalities *family assistance* and *other situations* are the ones presenting the lowest P.I.C.s, especially the latter, although it is also the least significant quantitatively.

If we look at table C.12 of the Annex, we will see that, as in previous years, there are transfers between some modalities, the most notable one taking place between *family assistance* and *business people without employees and independent workers*, since, of the total number classified in R.I. in the modality *family assistance*, 26 percent are classified in O.I. as *businesspersons without wage earners and independent workers*. Nevertheless, the effect of this transfer is very small, given the negligible number of persons classified in the modality *family assistance*.

On the other hand, of the persons classified as *employers* in R.I., 16 percent are classified as *business people without employees and independent workers* in O.I., although this transfer is not overly significant either in quantitative terms.

Regarding the characteristic *occupation*, we can see that the global consistency index stands slightly above 84 percent, which represents a notable improvement (approximately twelve percentage points) as compared with the value obtained in 2006. Nevertheless, its quality indicators (see table I.7) are generally worse than those for other characteristics assessed, due to the actual complexity in its classification.

Table I.7 shows that the lowest P.I.C.s correspond to *Management of companies and Public Authorities* and to *Armed Forces*, with 72 percent, and the highest to *Workers in services sector*, where it reaches a value of 91 percent.

Regarding biases, we can see that they are rather small and that they do not follow a specific trend, and the indices of gross change are not, generally, excessively high.

For the characteristic *branch of activity* the global consistency index shows a value of 91 percent. The modality presenting the lowest P.I.C. (see table I.8 in the Annex) is that of *Mining and quarrying industries*, where it stands at 57 percent, and the one presenting the highest is *Education*, with a P.I.C. of 97.4 percent. The modality *Production and distribution of electrical energy, gas and water supply* is the one presented by the highest net and gross change indices; nevertheless, it is in this, without considering *Extraterritorial institutions*, where the lowest number of personas is classified, therefore its indicators are not very significant.

#### 6.2.4. EMPLOYED POPULATION

The employed population is composed of all persons aged 16 years old or over who, in the reference week, had a job working for others or carried out a freelance activity, even if they did not work during the aforementioned week, or only did so partially for some reason. For this group of persons the following characteristics are studied: *hours worked in the main activity, number of hours worked equal or different to usual, reasons for working a different number of hours to usual and time that they have been working in their current job*. In addition, for employed persons the characteristic *type of contract* is studied, and for employees with a temporary contract, *its duration by public or private sector*. The results are shown in tables C.15 to C.20 of the Annex.

### 18. Global consistency indices

Feature	G.C.I.
Hours worked in the main job	70.73
No. of hours worked the same as or different than the normal hours worked	90.75

The global consistency indices of the first two characteristics are shown in chart 18, and it can be verified that both have increased significantly as compared with those obtained in 2006, particularly that corresponding to hours worked.

In the characteristic *hours worked in the main activity* the modality presented by the highest P.I.C. is *Between 1 and 9 hours*, therein reaching a value of 94 percent, this being the modality in which the lowest number of persons is classified (see tables I.9 and C.15 in the Annex). Conversely, the modality with the lowest P.I.C. is *Does not know*, with 40 percent.

Regarding biases, we can see that, although with a different sign, the highest correspond to the previous modalities, but are not very high. As far as the indices of gross change are concerned, they may generally be classed as moderate.

Table C.16 in the Annex includes *employed persons according to whether they worked a number of hours equal or different to usual*. It can be seen therein that the total number of employed persons classified by number of hours worked, approximately 76 percent, is classified in R.I. in *worked an equal number of hours*. Similarly it should be noted that the number of persons classified in *worked a greater number of hours* is very small, therefore its indicators are not very significant.

Table I.10 of Annex shows the quality indicators for this characteristic, the best ones corresponding to persons who *worked an equal number of hours*, with small net and gross change indices and with a P.I.C. standing at almost 94 percent.

With regard to *reasons for working a different number of hours to usual*, it is important to emphasise that persons classified as having worked a greater

number hours than usual are so few (please see chart 17 in the Annex) that they are not worth remarking upon.

## **19. Reasons to work fewer hours than normal (P.I.C.)**

Reason	P.I.C.
Holidays, leave, bank holidays	97.70
Maternity leave or extended leave of absence due	93.33
Illness, accident or temporary incapacity	100.00
Other reasons	97.37

As far as those employed persons working fewer hours than usual are concerned, 76 percent were classified in the modality *holiday, leave, public holidays*, there corresponding to this a fairly high P.I.C., as can be seen in chart 19. This chart only shows the four modalities into which a significant number of persons have been classified (please see table C.17 of the Annex).

## **20. Percentage distribution of the situation of the employed persons in O.I., who, according to R.I., worked the same number of hours as usual that week**

Situation in O.I.	Percentage
Does not know the number of hours worked	3.04
Worked the same number of hours as usual	91.09
Worked a different number of hours than usual	5.87
-Worked fewer hours than usual	4.53
Holidays, leave, bank holidays	2.29
Maternity leave or extended leave of absence	0.15
Illness, accident or temporary incapacity	1.19
Partial unemployment due to technical or	0.05
Labour force adjustment plan	0.00
Strike or labour conflict	0.00
Other reasons	0.80
Does not know	0.05
-Worked more hours than usual	1.34
Variable or flexible working hours	0.30
Overtime hours	0.85
Other reasons	0.10
Does not know	0.10

Chart 20 shows the percentage distribution of the situation, by E.O., of employed persons who, by R.I., worked an equal number of hours to usual in the week. We can see that 91 percent of these were classified in the same way in O.I., in other words, they also worked an equal number of hours to usual in R.I. 4.5 percent worked in O.I. fewer hours than usual, in the majority of cases due to *holiday, leave or public holidays* or due to *illness, accident or temporary incapacity*, as has occurred in previous years. Slightly over 1 percent worked more hours than usual, the majority of them due to *overtime hours*.

With regard to the characteristic *time that they have been working in their current job*, chart 21 shows the percentages of those identically classified. The modality presenting the best P.I.C. (95.6 percent) is *six years or over*, as has become commonplace, since it is the most significant modality in quantitative terms, since therein around 50 percent of the total number of those classified by time in the current job are classified. The remaining modalities also show relatively high P.I.C.s, since it exceeds 72 percent in all of these. The global consistency index stands at 87.4 percent, thereby increasingly considerably as compared with previous years.

## **21. Time working in the current job (P.I.C.)**

Modality	P.I.C.
Less than 3 months	81.65
From 3 months to less than 6 months	84.35
From 6 months to less than 1 year	73.56
From 1 year to less than 2 years	77.69
From 2 years to less than 3 years	72.35
From 3 years to less than 6 years	83.46
<b>6 years or more</b>	<b>95.60</b>

Within employed persons, *employees* are all persons working for a public or private company and receiving remuneration in return, whether in cash or in kind

Tables C.19 and C.20 in the Annex show the results of characteristics *employees by sex and type of contract or labour relationship* and *employees with a temporary contract, by public or private sector, and its duration*. The P.I.C.s for both characteristics are shown in charts 22 and 23, respectively.

## 22. Type of contract or labour relationship (P.I.C.)

Modality	P.I.C.
Indefinite duration	93.98
- Permanent	99.67
- Discontinuous	83.33
Temporary duration	91.24
- Temporary due to circumstances prod	88.89
- Apprenticeship, training or work exper	87.50
- Seasonal	92.86
- In the trial period	64.71
- Covering the absence of another work	88.46
- From a project or service	77.55
- Another type	47.76
- Does not know	53.19

Within the characteristics *type of contract or labour relationship*, we can see that the modality *indefinite duration* shows the highest P.I.C.s, in general, than the modality *temporary duration*, continuing the trend of previous years. Of note is the P.I.C. approaching the 100 percent obtained in the submodality *permanent* of the modality *indefinite duration*. The different submodalities of *temporary duration* show somewhat higher P.I.C.s than in 2006, but are, except for *project or service*, of little quantitative significance.

The G.C.I. of the characteristic *type of contract or labour relationship* reaches a value of 86.8 percent, thereby increasing as compared with previous years.

As far as the characteristic *duration of the temporary contract is concerned, by public or private sector*, the global consistency index stands at 69.7 percent, a value somewhat higher than the one obtained in 2006.

In the first place, it is necessary to say that there a few persons to classify according to this characteristic, the majority of whom are in the modality *private sector*, with 82 percent, as shown in table C.20 in the Annex. Therefore, the modality *public sector* is of very little importance in quantitative terms, therefore the P.I.C.s of their submodalities, whose values can be seen in chart 23, are of very little significance.

The P.I.C.s for the modality *private sector* are more significant and their values may likewise be seen in chart 23. It may be said generally that they are higher than those corresponding to 2006.

## 23. Duration of the temporary contract (P.I.C.)

Duration	P.I.C.
Public sector	94.62
- One day	-
- From 2 days to less than 1 month	100.00
- 1 to 3 months	90.91
- 4 to 11 months	100.00
- From 1 year to less than 3 years	75.00
- 3 years or more	75.00
- Does not know, but less than 1 month	100.00
- Does not know, but more than 1 month	57.14
- Does not know	66.67
Private sector	98.40
- One day	100.00
- From 2 days to less than 1 month	83.33
- 1 to 3 months	87.93
- 4 to 11 months	81.61
- From 1 year to less than 3 years	59.26
- 3 years or more	50.00
- Does not know, but less than 1 month	0.00
- Does not know, but more than 1 month	68.62
- Does not know	55.56

### 6.2.5. UNEMPLOYED POPULATION

Unemployed persons are regarded as all those aged 16 years old or over who, in the reference week, simultaneously meet the following conditions:

- Are not working.
- Are seeking work, or if not, it is because they have already found a job, which they will be starting at a date subsequent to the reference week.
- Are available to work.

From this group of active persons, by repeat interview procedure, the quality of the characteristics *type of unemployed*, distinguishing between males and females, *economic sector* and *time that they have been seeking work* (tables C.21 to C.23 in the Annex) is assessed.

In *type of unemployed* a distinction is made between those applying for their first position of employment and those who have worked previously.

Chart 24 shows the net change indices for unemployed persons by sex and type of unemployed, and we are able to see that they only reach a high value in the case of males applying for their first position of employment. We can also see that those corresponding to applying for their first position of employment are positive, whereas those relating to persons who have worked previously are negative, irrespective of sex. Conversely, chart 25 shows that the G.C.I. of females is higher than that of males.

## **24. Unemployed persons, by sex and type (I.C.N.)**

### Sex / type of unemployed person I.T.I.

#### Men

- Total	0.00
- Seeking first job	30.00
- Have worked previously	-3.80

#### Women

- Total	0.00
- Seeking first job	5.00
- Have worked previously	-0.86

Regarding the *economic sector*, its G.C.I. reaches a value in the region of 95 percent (chart 25), thereby experiencing a considerable increase as compared with the one obtained in 2006.

Lastly, the low quality of the characteristic *job search time* should be highlighted, having the lowest global consistency index of those assessed, standing at 76.4 percent, a value nonetheless much higher than the one obtained in 2006.

## **25. Global consistency indices**

Feature	G.C.I.
Type of unemployed person	95.56
- Men	94.38
- Women	96.32
Economic sector	94.85
Time spent on the job search	76.38

---

#### 6.2.6 CONCLUSION

On analysing previous charts, it has been possible to see that, even though there are differences between the different characteristics, the quality of data from the APS remains within fairly acceptable limits. It is worth highlighting that the O.I.-R.I. is performed by computer, once both the O.I. and the R.I. data have been submitted to different filtering and imputation processes. The only difference in processing O.I. and R.I. data stems from the fact that, whereas some O.I. data is imputed by means of a random procedure (DAY), in the R.I. data no random imputation procedure is used.

Conversely, any difference between O.I. and R.I. is counted as a content error, although it may be due to lapses of memory or to discrepancies in interpreting the question, where the informant is not the same in the two interviews. Similarly, in some characteristics whose modalities are not mutually exclusive, classification is difficult to specify in practice.

---

### 6.3 Other applications of the assessment interview

---

#### 6.3.1. STUDY OF THE INFLUENCE OF THE INFORMANT ON THE QUALITY OF THE RESULTS

In order to analyse the possible influence on the quality of the results of the fact that the informant has been the same or different in the two interviews (O.I. and R.I.), the joint O.I.-R.I. information from the four quarters and relating to the population aged 16 years old and over, has been separated into two blocks, one corresponding to the dwellings in which the informant was the same in both interviews and another corresponding to the dwellings in which the informant was different therein.

In order to study the influence of this variable, the characteristics *relation to the activity* and *educational level* have been selected, since they are regarded as being a great interest.

To this end, for each of the aforementioned blocks corresponding coincidence tables have been prepared for each of said characteristics and their corresponding quality indicators have been calculated. The results obtained for the *relation to the activity* can be seen in charts 26 to 28 and for *educational level* in charts 29 to 31.

## 26. Persons 16 years old and over by O.I. and R.I., by relationship with economic activity. Same informant

Classification according to R.I.	Classification according to O.I.	Total	Active persons			Unemployed persons			Inactive persons
		Total	Employed persons	Total	Seeking their first job	Have worked before			
Total persons	4,384	2,178		1,990	188				2,206
Active persons									
Total	2,224	2,127		1,962	165	24	141	97	
Employed persons	2,003	1,963		1,954	9	.	9	40	
Unemployed persons									
Total	221	164		8	156	24	132	57	
Seeking 1st job	27	22		1	21	18	3	5	
Have worked before	194	142		7	135	6	129	52	
Inactive persons	2,160	51		28	23	1	22	2,109	

## 27. Persons 16 years old and over according to O.I. and R.I., by relationship with economic activity. Different informant

Classification according to R.I.	Classification according to O.I.	Total	Active persons			Unemployed persons			Inactive persons
		Total	Employed persons	Total	Seeking their first job	Have worked before			
Total persons	1,928	1,028		936	92	18	74		900
Active persons									
Total	1,026	991		915	76	10	66	35	
Employed persons	936	916		909	7	.	7	20	
Unemployed persons									
Total	90	75		6	69	10	59	15	
Seeking 1st job	16	10		1	9	9	.	6	
Have worked before	74	65		5	60	1	59	9	
Inactive persons	902	37		21	16	8	8	865	

With regard to the first of these characteristics (*relation to the activity*), in view of the figures in chart 28, it may be said that there are no great differences between the indicators in both cases, since the G.C.I.s and P.I.C.s are fairly similar with both types of informant (the main difference, by six points, is in the P.I.C. for unemployed persons, which is greater in the case of different informant). Regarding the net change indices, we can see that in all modalities they are smaller, in absolute value, in the case of a different informant, in addition having different sign in each of them.

With regard to population transfers between unemployed and inactive persons, these are greater in the case of the same informant, since almost 26 percent of

those classified as unemployed in R.I. are classified as inactive in O.I., since this percentage is approximately 17 percent in the case of a different informant.

## 28. Quality indicators. Relationship with economic activity with the same or a different informant

Relationship with economic activity	Percentage of Identically Classified Informant		Global Net Change		Index of Consistency Indices	
	Informant		Informant		Informant	
	Same	Different	Same	Different	Same	Different
Active persons	95.64	96.59	-2.07	0.19	-	-
Employed persons	97.55	97.12	-0.65	0.00	-	-
Unemployed persons	70.59	76.67	-14.93	2.22	-	-
Inactive persons	97.64	95.90	2.13	-0.22	-	-

In view of these results, it may be concluded that the fact that the informant is the same or different in the two interviews does not significantly influence classification of the population by relation with the economic activity.

Charts 29 and 30 show the persons classified in O.I. and R.I. by educational level for the same and a different informant.

## 29. Persons 16 years old and over according to O.I. and R.I., by educational level. Same informant

Classification according to R.I.	Classification according to O.I.	Educational level						
		Total	Illiterate	Primary	Secondary education		Higher education, except doctorates	Doctorate
					First stage	Second stage		
Total persons		4,384	138	1,770	1,007	708	750	11
Does not know educational level		10	2	5	1	1	1	-
Total classified		<b>4,374</b>	136	1,765	1,006	707	749	11
Illiterate		184	<b>118</b>	65	1	-	-	-
Primary education		1,776	16	<b>1,562</b>	169	22	7	-
Secondary education								
- First stage		955	-	119	<b>783</b>	47	6	-
- Second stage		690	1	16	48	<b>588</b>	37	-
Higher education, except doctorates		758	1	3	5	50	<b>697</b>	2
Doctorate		11	-	-	-	-	2	<b>9</b>

### 30. Persons 16 years old and over according to O.I. and R.I., by educational level. Different informant

Classification according to R.I.	Classification according to O.I.	Educational level						
		Total	Illiterate	Primary education	Secondary education	Higher education, except doctorates	Doctorate	
				First stage	Second stage			
Total persons		1,928	50	699	440	398	335	6
Does not know educational level		4	-	1	2	1	-	-
Total classified		<b>1,924</b>	50	698	438	397	335	6
Illiterate		67	<b>41</b>	26	-	-	-	-
Primary education		701	9	<b>594</b>	79	14	5	-
Secondary education								
- First stage		434	-	65	<b>326</b>	35	8	-
- Second stage		368	-	6	27	<b>314</b>	21	-
Higher education, except doctorates		348	-	7	6	34	<b>301</b>	-
Doctorate		6	-	-	-	-	-	<b>6</b>

If we analyse the results obtained, observing the indicators shown in chart 31, we can see that these are somewhat better in the case of the same informant, the differences generally being greater between same and different informant than in the case of relation to the activity.

### 31. Quality indicators. Level of training with the same or a different informant

Educational level	Percentage of Identically Classified Informant		Index of Net Change Informant		Global Consistency Indices Informant	
	Same	Different	Same	Different	Same	Different
Illiterate	64.13	61.19	-26.09	-25.37	-	-
Primary education	87.95	84.74	-0.62	-0.43	-	-
Secondary education						
- First stage	81.99	75.12	5.34	0.92	-	-
- Second stage	85.22	85.33	2.46	7.88	-	-
Higher education, except doctorates	91.95	86.49	-1.19	-3.74	-	-
Doctorate	81.82	100.00	0.00	0.00	-	-

In the modality *doctorate* is the one in which fewest persons are classified, therefore their indicators are in no way significant.

The P.I.C. is greater with the same informant than with a different one in a greater number of modalities.

As regards the distortion (I.C.N.), no clear trend can be seen in its magnitude towards one case or another, having the same sign in both cases for all modalities.

Population transfers between modalities (see charts 29 y 30) are similar in both cases. Worth noting were the following: 35 percent of those classified in R.I. as *illiterate* are classified in O.I. in *primary education* when the informant is the same, whereas when the informant is different, this percentages rises to 39 percent; 12.5 percent of persons classified in R.I. in *secondary education, first stage*, are classified in O.I. in *primary education* when the informant is the same, standing at 15 percent in the case of a different informant.

With these results we cannot state that the fact that the informant is the same or different in the two interviews has a decisive influence on the classification of the population by level of education attained.

## **5. Quality indicators**

**Table I.1**  
**Population aged 16 years old and over, by age group**

Quality indicators

Age groups	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
16 to 19 years old	98.77	0.03	0.62	0.16	3.08
20 to 24 years old	98.85	-0.03	-0.46	0.13	1.85
25 to 29 years old	99.08	-0.02	-0.23	0.11	1.61
30 to 34 years old	98.89	0.00	0.00	0.16	2.21
35 to 39 years old	99.21	0.05	0.59	0.17	2.16
40 to 44 years old	99.51	0.03	0.33	0.13	1.32
45 to 49 years old	98.24	-0.08	-0.88	0.24	2.65
50 to 54 years old	99.38	0.03	0.41	0.13	1.66
55 to 59 years old	99.16	0.10	1.26	0.22	2.93
60 to 64 years old	98.84	-0.06	-0.93	0.10	1.39
65 to 69 years old	99.49	0.03	0.51	0.10	1.52
70 years old and over	99.33	-0.08	-0.42	0.17	0.92

**Table I.2**  
**Population aged 16 years old and over, by marital status**

Quality indicators

Marital status	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Single persons	97.78	0.00	0.00	1.24	4.45
Married persons	99.09	0.27	0.45	1.35	2.27
Widowed persons	97.92	0.11	1.22	0.49	5.38
Separated or divorced persons	86.07	-0.38	-9.84	0.70	18.03

**Table I.3**  
**Population aged 16 years old and over by nationality**

Quality indicators

Nationality	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Spanish	99.67	-0.19	-0.20	0.44	0.46
Spanish and another	85.19	-0.02	-3.70	0.11	25.93
Foreign	96.76	0.21	6.02	0.43	12.50

**Table I.4**  
**Population aged 16 years old and over, by educational level attained**

Quality indicators

Educational level	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Illiterate	63.35	-1.03	-25.90	1.89	47.41
Primary education	87.04	-0.22	-0.57	9.97	25.35
Secondary education					
-First stage and training and corresponding labour insertion	79.84	0.87	3.96	9.77	44.28
-Second stage and training and corresponding labour insertion	85.26	0.73	4.35	5.68	33.84
Higher education, except doctorates	90.24	-0.35	-1.99	3.08	17.54
Doctorate	88.24	0.00	0.00	0.06	23.53

**Table I.5**  
**Population aged 16 years old and over, according to  
relationship with economic activity**

Quality indicators

Relationship with economic activity	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Active persons	95.94	-0.70	-1.35	3.49	6.77
Employed persons	97.41	-0.21	-0.44	2.20	4.73
Unemployed persons	72.35	-0.49	-9.97	2.23	45.34
Seeking 1st job	62.79	0.00	0.00	0.51	74.42
Have worked previously	70.15	-0.49	-11.57	2.04	48.13
Inactive persons	97.13	0.70	1.44	3.49	7.18
Incapacitated persons	68.18	-0.06	-2.60	1.49	61.04
Students	91.75	0.02	0.24	1.09	16.75
Retired persons	92.27	-0.32	-1.30	3.45	14.17
Homemakers	90.57	1.00	7.07	3.66	25.93
Another situation	51.52	0.06	6.06	1.08	103.03

**Table I.6**  
**Economically active population by situation  
status**

Quality indicators

Professional status	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Employers	79.63	-0.23	-4.32	1.96	36.42
Businesspersons without employees	89.38	0.76	6.78	3.15	28.02
Members of cooperatives	81.82	-0.03	-9.09	0.10	27.27
Family assistance	60.87	-0.03	-2.17	1.16	76.09
Wage earners	98.65	-0.20	-0.25	1.99	2.45
Public sector employees	95.72	0.03	0.21	1.36	8.78
Private sector employees	97.43	-0.23	-0.35	3.15	4.80
Other situations	20.00	-0.27	-80.00	0.27	80.00

**Table I.7**  
**Economically active population by occupation**

Quality indicators

Occupation	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Business administration and Public Administration	72.22	-0.46	-6.48	3.51	49.07
Scientific and intellectual technicians and professionals	90.18	-0.46	-4.29	1.66	15.34
Support technicians and professionals	77.85	0.93	9.40	5.30	53.69
Administrative type employees	77.52	0.00	0.00	3.84	44.96
Workers in services	91.12	0.56	3.59	3.35	21.35
Workers in agriculture and fishing	81.08	-0.40	-10.81	0.99	27.03
Craftspersons and workers in the manufacturing, construction and mining industries	83.97	-1.26	-6.34	5.10	25.71
Installation and machinery operators, fitters.	86.38	0.17	1.66	2.88	28.90
Unskilled workers	87.35	1.09	7.88	4.60	33.17
Armed Forces	72.22	-0.17	-27.78	0.17	27.78

**Table I.8**  
**Economically active population by branch of activity**

Quality indicators	(Next)				
Branch of activity	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Agriculture, livestock, hunting and forestry	93.10	-0.03	-0.57	0.76	13.22
Fishing	90.91	-0.03	-9.09	0.03	9.09
Mining and quarrying industries	57.14	-0.07	-14.29	0.33	71.43
Manufacturing industries	90.11	-0.23	-1.51	2.82	18.28
Production and distribution of electrical engineering, gas and water	66.67	0.10	50.00	0.23	116.67
Construction	92.41	0.17	1.15	2.36	16.32
Trade, repair of motor vehicles and personal and household use items	92.40	-0.23	-1.40	2.29	13.80
Accommodation	92.67	-0.17	-2.62	0.76	12.04
Transport, storage and communications	91.84	0.03	0.68	0.83	17.01
Financial intermediation	97.06	0.00	0.00	0.13	5.88
Real estate and rental activities; business services	85.11	0.40	5.11	2.72	34.89
Public Administration, defence and compulsory social security	94.61	0.33	4.90	1.06	15.69
Education	97.39	0.23	4.58	0.50	9.80
Health and veterinary activities; social services	92.82	-0.17	-2.56	0.76	11.79
Other social activities and community service activities	79.20	-0.20	-4.80	1.53	36.80
Household activities such as employers of domestic staff	85.23	-0.10	-3.41	0.76	26.14
Extraterritorial institutions	-	-	-	-	-

**Table I.9**  
**Employed persons, by hours worked in the main job**

Quality indicators

Hours worked	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
No hours	90.45	1.05	15.08	2.38	34.17
1 to 9 hours	94.12	0.28	23.53	0.42	35.29
10 to 19 hours	76.19	0.38	13.10	1.78	60.71
20 to 29 hours	76.26	0.70	9.13	4.33	56.62
30 to 39 hours	69.83	-2.10	-10.34	10.13	50.00
40 to 49 hours	83.31	-0.17	-0.39	14.84	33.00
50 or more hours	78.46	1.71	18.85	5.62	61.92
Does not know	40.20	-1.85	-26.63	6.46	92.96

**Table I.10**  
**Employed persons, according to whether they worked the same  
or a different number of hours than the normal hours worked**

Quality indicators

Reasons	P.I.C.	N.R.D.	I.T.I.	G.R.D.	G.C.I.
Worked the same number of hours	93.94	-0.12	-0.15	9.06	11.96
Worked a different number of hours	81.57	0.12	0.48	9.06	37.34
Worked fewer hours	82.16	-0.19	-0.90	7.50	34.77
Worked more hours	69.57	0.31	11.59	1.94	72.46
