

INSTITUTO NACIONAL DE ESTADISTICA

**Quality evaluation of the
data from the Economically
Active Population Survey**

Year 2011

Foreword

Since 1971, the National Statistics Institute has carried out a quality assessment programme of the Economically Active Population Survey. Its purpose is to make information available regarding sampling errors and errors not related to sampling, which enables, on the one hand, making opportune decisions on the perfection of the methods, and on the other hand, to provide the user with information regarding the quality of the data offered.

The current publication offers the results obtained in the year 2011, linked with the previous publications on quality evaluation of the Economically Active Population Survey.

The National Statistics Institute would like to express its gratitude to the families that have provided the information requested, and to everybody who has been involved in this work.

Gregorio Izquierdo Llanes

INE President

Introduction

On evaluating the quality of the results of statistics, the goal is to achieve two fundamental objectives:

- To detect the errors that have been produced during the different stages of their compilation.
- To provide users with detailed information regarding the quality of the data that they deal with.

The detection of the errors produced should not be reduced to a mere numerical presentation of them. The primordial objective should be their analysis, in order to decipher the possible causes leading to them. This is important, even essential, in all statistics, so as to improve the quality thereof. Continuous surveys such as the Economically Active Population Survey (EAPS) also include the attraction of the immediate collection of their results, avoiding in parallel the deterioration of the quality of all of the routine work that this type of survey entails. To reduce the errors unrelated to sampling allows us to improve the quality of the estimates, for the purpose of obtaining acceptable levels of error, and maintaining them over time, which allows for a more adequate study of the resulting time series.

On assessing the results of an evaluation programme, it is necessary to bear in mind the conditioning factors under which the surveys are conducted, which prevent, in many cases, avoiding the errors detected later in the evaluation, with the compilers of the statistics still being aware of the possibility of their presence. However, the supply of the information on the limitations of the data is an unavoidable duty, since an inappropriate use of the figures can cause the failure of socio-economic and demographic plans and projects, and falsify conclusions on measures developed by politicians, economists and the remaining users of the statistics.

In the EAPS, the quality evaluation has been extended in subsequent stages to the different phases of the survey; this is currently one of the most complete evaluation programmes worldwide. The information obtained has been used to introduce amendments to the methodology applied, aimed at improving data quality. The user is provided with results of the evaluation of varying lengths in three types of publication: quarterly in *Main Results and Detailed Results* and annually, in monographic reports such as this one, dedicated exclusively to data quality.

This volume offers data regarding the quality of the survey for the year 2011.

1. Quality of the data and total error

When we try to estimate a population parameter with the data from a sampling survey, under the hypothesis that we are using an appropriate estimator, an estimate thereof will be of high quality if the data on which it is based is of high quality. Conversely, if the survey data is of low quality, the estimates will also be of low quality.

However, the sample size on which the estimates are based also constitutes an important determining factor of quality. Even if the data is high quality, an estimate based on a very small number of observations will scarcely be reliable. Therefore, the quality of an estimator of a population parameter is a function of the **total survey error**, which encompasses an error deriving solely from the fact of selecting a sample rather than carrying out a complete census, called **sampling error**, as well as other error related to the data collection and processing procedures, known as **errors other than sampling errors**.

Non-sampling errors may occur during any phase of the statistical process. Despite the greatest efforts to avoid them, errors other than sampling errors are particularly inevitable in large-scale data collection operations (such as censuses).

In the case of sampling errors their magnitude may be controlled by adjusting the size of the sample. Therefore, the sampling error can be as small as we want or can afford, without doing anything other than increasing the size of the sample.

In recent years, researchers have discovered that, in many cases, errors other than sampling errors can be much more harmful, for the estimates, than sampling errors.

The optimisation of the sample design implies finding a balance between the sampling errors and the errors other than sampling errors, in such a way that the total error is as small as possible for the available budget.

Errors other than sampling errors can come from five main sources:

- **Specification errors:** these errors occur when what we are trying to measure or verify through the survey does not coincide with what is actually asked in the survey, due to the fact that there are concepts or definitions that are not well specified. These are frequently caused by poor communication between the researcher or promoter of the survey and the person or persons who design the survey questionnaire.
- **Framework errors:** these take place when there are elements of the population that are omitted or duplicated within the sampling framework, or when there are elements included therein that should not be (erroneously included elements).
- **Errors due to non-response:** three types are distinguished:
 - o **Non-response of the unit:** this occurs when an element of the sample does not participate in the sample, due to different reasons (refusal to participate, absence, unlocatable, etc.).

- **Non-response to one or more questions:** this occurs when the questionnaire has been only partially completed, due to there being questions that have remained unanswered (in surveys aimed at households, a typical example are those questions referring to household income).
 - **Incomplete response:** this occurs when, in open questions, the informant provides some information, but the answer is too short to allow for adequate encoding.
 - **Measurement errors:** these errors are fundamentally due to the informant, the interviewer and the questionnaire of the survey. Informants may give, whether deliberately or not, incorrect information. Interviewers may falsify data, inappropriately influence responses, incorrectly register responses, etc. The questionnaire may contain ambiguous questions, confusing instructions, etc.
- This modality also includes those errors that might come from the information collection method used. Finally, the framework or scenario in which the interviews are conducted can contribute to increasing measurement errors (for example, in surveys dealing with somewhat sensitive subjects).
- **Processing errors:** these are errors that occur during the data processing stage, including errors in recording, encoding, assignation of weightings and data tabulation, among others.

The total error is the difference between the true value of the population parameter and the estimation thereof, based on the sample selected. Due to the fact that the true value of the population parameter is unknown, the total error of an estimate will likewise be unknown, but can be approached using special methods for evaluating surveys.

The development of the survey design implies many decisions that can affect the total error of an estimate. There are decisions with regard to the size of the sample, the collection method, the training and supervision of the interviewers, the design of the questionnaire, etc., which in the long run will determine the quality of the survey data.

An important support when designing a survey is to have a means of quantifying the total error, since this makes it possible to compare alternative designs, not only on the basis of cost and punctuality in the dissemination of the data, but also considering its total error.

There are many ways of quantifying the total error associated with an estimate obtained from a survey. One of the most frequently used measurements is the *total average square error*, which measures the magnitude of the total error, or more precisely, the magnitude of the effect of the total error on the estimate in question. A small average square error indicates that the total error is likewise small and under control. A large average square error indicates that one or more sources of error are adversely affecting the accuracy of the estimate.

Unfortunately, it is not possible to calculate the average square error regularly, directly from the survey data, and in particular, when the data is subject to significant errors other than sampling errors. Many situations require special assessment studies, supplementary to the main survey, in order to measure the total average square error.

For years, in order to assess the quality of the data, the EAPS has used the method of the **repeat interview**, which consists of repeating the interview, shortly after having conducted the original interview, of a part of the surveyed units. Through the comparison of the data collected in both interviews for the same units, it is possible to estimate the quality of the results, and provide the users with some numerical indices regarding said quality. This procedure is based on the model by Hansen, Hurwitz and Bershad, applied by the United States Census Office.

In relation to this model, it is appropriate to mention that more progress has been made in individualised analysis of the influence of certain factors giving rise to errors, and in applying controls and imputation methods for resolving them, than in evaluating the overall effect of sampling errors and errors other than sampling errors on the results. The first line contains evaluations carried out by the INE in the EAPS.

In the following sections of this report, the different types of error are analysed individually, indicating the methodology applied for their assessment.

2. Sample errors

2.1 Methodology

For the calculation of the sampling errors, the EAPS applies the method of repeated semi-samples, which allows for estimating the variance of an estimator \hat{X} by means of the formula:

$$\hat{V}(\hat{X}) = \frac{1}{r} \sum_i^r (\hat{X}_i - \hat{X})^2$$

where:

r is the number of repetitions used

\hat{X}_i is the estimate obtained with the i -th repetition

\hat{X} is the estimate obtained with the complete sample

Each repetition is a subsample comprising a number of sections equivalent to 50 per cent of the complete sample. The number of repetitions used in the EAPS has been set at 40. In order to form them, sections of each stratum are grouped into pairs, and the first section of each pair is randomly assigned to 20 repetitions, and the second to the remaining 20. Thus, each section appears in half the repetitions, and the number of sections in each repetition is equal to 50 percent of the complete sample.

This repetition structure remains indefinitely, thus enabling the calculation of the sampling error of any survey estimate without further programming problems, in theory, than applying 40 times the same formula of the estimator used in the survey, and finding the square mean of the values estimated on the basis of the 40 repetitions as compared with the estimate based on the complete sample.

The calculation of the estimates taken from the semi-samples is carried out in the same way as with the complete sample, that is, by means of a ratio estimator calibrated by age group and sex and population total by province.

2.2 Presentation of sampling errors

In the tables of this document, the sampling error is presented as a variation coefficient, in other words, expressed as a percentage of the estimate, with the following **formula**:

$$C\hat{V}(\hat{X}) = \frac{\sqrt{\hat{V}(\hat{X})}}{\hat{X}} \cdot 100$$

Variation coefficients have been calculated for the following characteristics:

National level

- 1) Active persons by age group and sex (table E.M.2)
- 2) Persons employed part-time by economic sector and sex (table E.M.10)
- 3) Active persons by branch of activity and sex (table E.M.3)
- 4) Unemployed persons by economic sector and sex (table E.M.4)
- 5) Inactive persons by age group and sex (table E.M.5)
- 6) Employed persons by economic sector and sex (table E.M.8)
- 7) Wage earners by economic sector and sex (table E.M.9)
- 8) Inactive persons according to the reasons why they do not look for jobs, and sex (table E.M.10)
- 9) Inactive persons by type of inactivity and sex (table E.M.13)

Autonomous and provincial levels

- 1) Population aged 16 years old and over, according to relationship with economic activity, by province (tables E.M.6)
- 2) Population aged 16 years old and over, according to relationship with economic activity, by Autonomous Community (tables E.M.7)

The data provided in these tables makes it possible to have an approximate idea of the reliability of the different survey estimates. In general, the greater the level of breakdown of the figures, the greater the resulting sampling error, and therefore the lesser the accuracy of the estimate.

2.3 Use of the tables

When calculating and publishing the sampling error, the statistician provides the user with a means of obtaining a numerical interval that has certain confidence (measured in probability terms) of containing the real value that we wish to estimate.

Sampling theory determines that, under certain hypotheses considered complied with in this survey, in the interval included between the estimate less 1.96 times the sampling error and the estimate plus 1.96 times the sampling error there is a 95% confidence interval of finding the true value or parameter aimed to be estimated. From here on, this interval is called the 95% *confidence interval*. It may be interpreted that, on average, of each 100 samples obtained under the same design and general conditions, these confidence intervals obtained from each of them would contain the real value 95 times out of a 100.

From the estimate and its sample error, other confidence intervals may be formed with similar interpretation, for example:

estimate \pm twice the sample error = confidence interval of 95%.

estimate \pm Twice the sample error = 95 percent confidence interval.

estimate \pm twice the sample error = confidence interval of 99.7%%.

For example, the estimate of the total unemployed persons in the country in the third quarter of 2011 is 4,978,300 with a relative sampling error of 1.05 percent. This means that there is a great deal of confidence, measured in terms of probability, a confidence of 95%, of which the real value of total unemployed persons will be within the interval between 4,873,756 and 5,082,844 (that is, $4,978,300 \pm 2 \times 52,272$).

It can be concluded that it is up to the user to determine whether or not a figure with a certain sampling error is useful to him or her for making decisions, in accordance with the degree of reliability needed for this.

The magnitude of relative sampling errors may invalidate certain provincial estimates; nevertheless, the latter may be useful if grouped by Autonomous Community in accordance with the needs of each user. In these cases, an estimate of the relative sampling error may be obtained by means of the formula:

$$\hat{CV}(\hat{X}) = \frac{1}{\sum \hat{X}_h} \sqrt{\sum (\hat{X}_h \cdot \hat{CV}(\hat{X}_h))^2}$$

where:

$\hat{CV}(\hat{X})$ = estimate of the relative sampling error in the Autonomous Community.

\hat{X}_h = the estimation of the characteristic in the h-th province.

$\hat{CV}(\hat{X}_h)$ = estimate of the relative sampling error in the h-th province,

with the sums extended to all provinces in the Autonomous Community.

Tables E.M.7 present the corresponding relative sampling errors for the Autonomous Communities as a percentage.

3. Non-response

In the EAPS, the sample selection is carried out through a two-stage sampling, selecting, in the first stage, a given number of census sections, and in the second stage, a given number of dwellings in each one of the previously selected sections.

The selected dwellings remain in the sample for six consecutive quarters, after which they are replaced by other dwellings from the same section.

In order for there to be a considerable amount of common sample between two consecutive quarters (5/6 of the sample), the replacement of dwellings with others is staggered, whereby each quarter, one sixth of the sample is renewed, the part corresponding to those dwellings which were in the sixth interview the previous quarter. In order for this process to be easy to carry out, the sample of sections is distributed into six parts or rotation shifts, in such a way that each quarter, the dwellings corresponding to the sections of a given rotation shift are renewed.

In the dwellings corresponding to the sections of the rotation shift in the first interview, solely the CAPI collection method is used. In the dwellings corresponding to shifts that are in their second and subsequent interviews, the CATI method is used primarily, only leaving for CAPI those dwellings without a telephone and those that, even though they have a telephone number, prefer to continue with the personal interview method in subsequent quarters. In other words, whereas the CAPI method is used in all of the interviews, the CATI method is only used in the second to sixth interviews (subsequent interviews).

The dwellings selected for the sample (incumbent households), according to the situation they are in at the time of interview, are classified into three types:

- **Unavailable dwellings:** in CAPI, those dwellings which are unreachable for conducting the interview are included under this designation, generally due to climatological causes (snowstorms, floods, etc.) or geographical causes, where there are no transitable roads to arrive there. This may also include the cases in which doormen or concierges, in those buildings in which there is such a person, do not allow access to the dwellings.

In CATI, those dwellings for which, despite having a contact telephone number, and even including those having been interviewed previously via the CATI system, it is not possible establish telephone contact, however often the calls are repeated, or obtain another contact number under this designation. Under these circumstances, attempts are made to interview the dwelling via the CAPI method, but if there is no longer enough time, they are ultimately classified as unavailable, and are passed on to CAPI for the second quarter.

- **Unsurveyable dwellings:** these are those dwellings that do not belong to the group being studied, due to not being used all year or most of the year as a habitual or permanent family residence. Included within this type are empty dwellings, secondary or seasonal dwellings, those intended in their entirety for purposes other than those of a family residence and those dwellings that are unreachable at the address shown on the work order (the latter are only possible in CAPI).

- **Surveyable dwellings:** these are the dwellings that are used the whole year or most of it as a permanent family residence. Within this type, there are cases in which data cannot be obtained from the occupants of the dwelling due to absence or refusal thereof to participate in the survey. These cases constitute what is known as *non-response*.

Table 1.1 shows the total incumbent dwellings selected in the four quarters of the year, broken down into the three types mentioned, whereas tables **1.1 and 1.3** show the breakdown of said dwellings, according to the collection method used, whether CATI or CAPI.

The processing, within the general process of the survey, of the unsurveyable dwellings, and of the dwellings of whose occupants information is not obtained (non-response), differs noticeably due to the characteristics and influence on the estimates of both types of incidence, as will be seen below.

1.1 Selected incumbent dwellings. Total

Dwellings	Quarter							
	First		Second		Third		Fourth	
	No.	%	No.	%	No.	%	No.	%
Total	89,002	100.00	88,082	100.00	88,886	100.00	88,972	100.00
- Inaccessible	1,249	1.40	1,265	1.44	1,280	1.44	1,178	1.32
- Unsurveyable	17,124	19.24	17,113	19.43	16,560	18.63	17,633	19.82
- Surveyable	70,629	79.36	69,704	79.14	71,046	79.93	70,161	78.86

1.2 Selected incumbent dwellings. CATI

Dwellings	Quarter							
	First		Second		Third		Fourth	
	No.	%	No.	%	No.	%	No.	%
Total	52,184	100.00	52,042	100.00	51,207	100.00	51,093	100.00
- Inaccessible	1,155	2.21	1,151	2.21	1,124	2.20	1,063	2.08
- Unsurveyable	838	1.61	884	1.70	994	1.94	1,012	1.98
- Surveyable	50,191	96.18	50,007	96.09	49,089	95.86	49,018	95.94

1.3 Selected incumbent dwellings. CAPI

Dwellings	Quarter							
	First		Second		Third		Fourth	
	No.	%	No.	%	No.	%	No.	%
Total	36,818	100.00	36,040	100.00	37,679	100.00	37,879	100.00
- Inaccessible	94	0.26	114	0.32	156	0.41	115	0.30
- Unsurveyable	16,286	44.23	16,229	45.03	15,566	41.31	16,621	43.88
- Surveyable	20,438	55.51	19,697	54.65	21,957	58.27	21,143	55.82

3.1 Unavailable dwellings

In the preceding paragraph the circumstances have been described, which must occur together in a dwelling in order for it to be considered inaccessible or unavailable. As mentioned above, this type of dwelling may appear either where data is collected using CAPI, or where this is done using CATI.

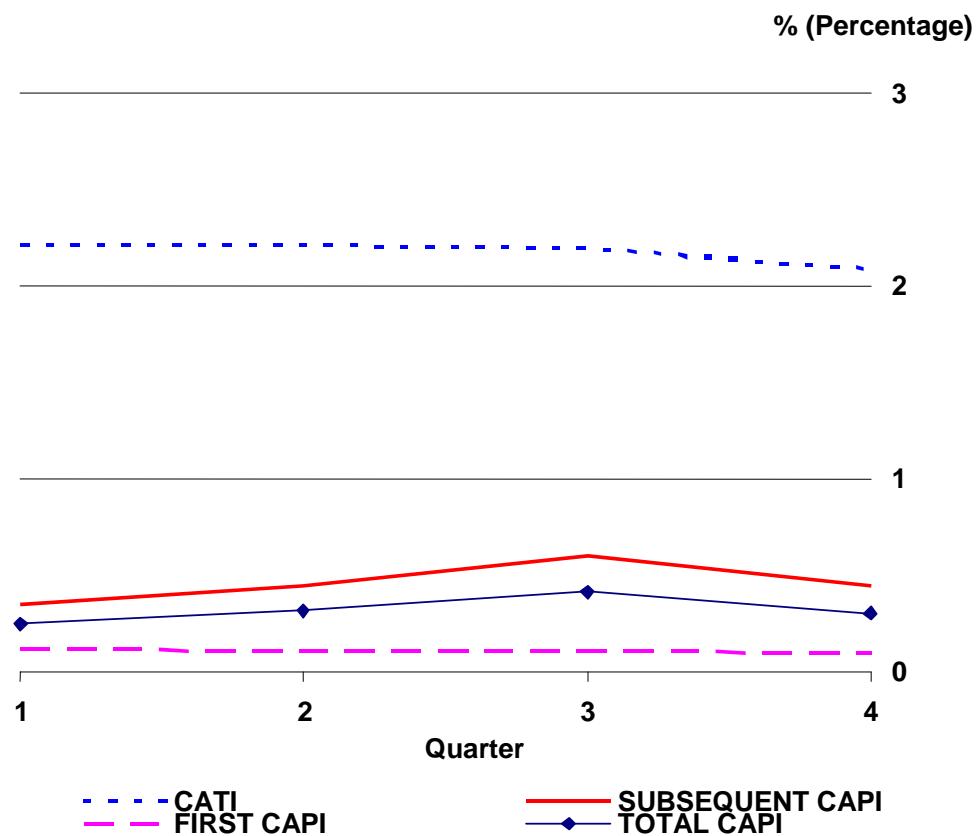

In the case of inaccessibility in CAPI, the interviewer waits for the causes of this to disappear, in order to be able to access the dwelling and conduct the

interview, insofar as the duration of the work in the section allows for this. Otherwise, the dwelling is finally considered inaccessible and revisited the following quarter.

In the case of inaccessibility in CATI, it is attempted to collect information by means of a personal interview, so long as this is feasible. Otherwise, the dwelling is finally considered inaccessible and revisited the following quarter, but assigning it to CAPI.

Graphs 1 and 2 represent the percentages of inaccessible dwellings, in the four quarters of the year, in the selected dwellings assigned to CATI, and in those assigned to CAPI. The percentages are calculated with regard to the corresponding number of selected dwellings. In the case of the latter collection method, a distinction is made between the first and subsequent interviews.

Graph 1 Inaccessible dwellings

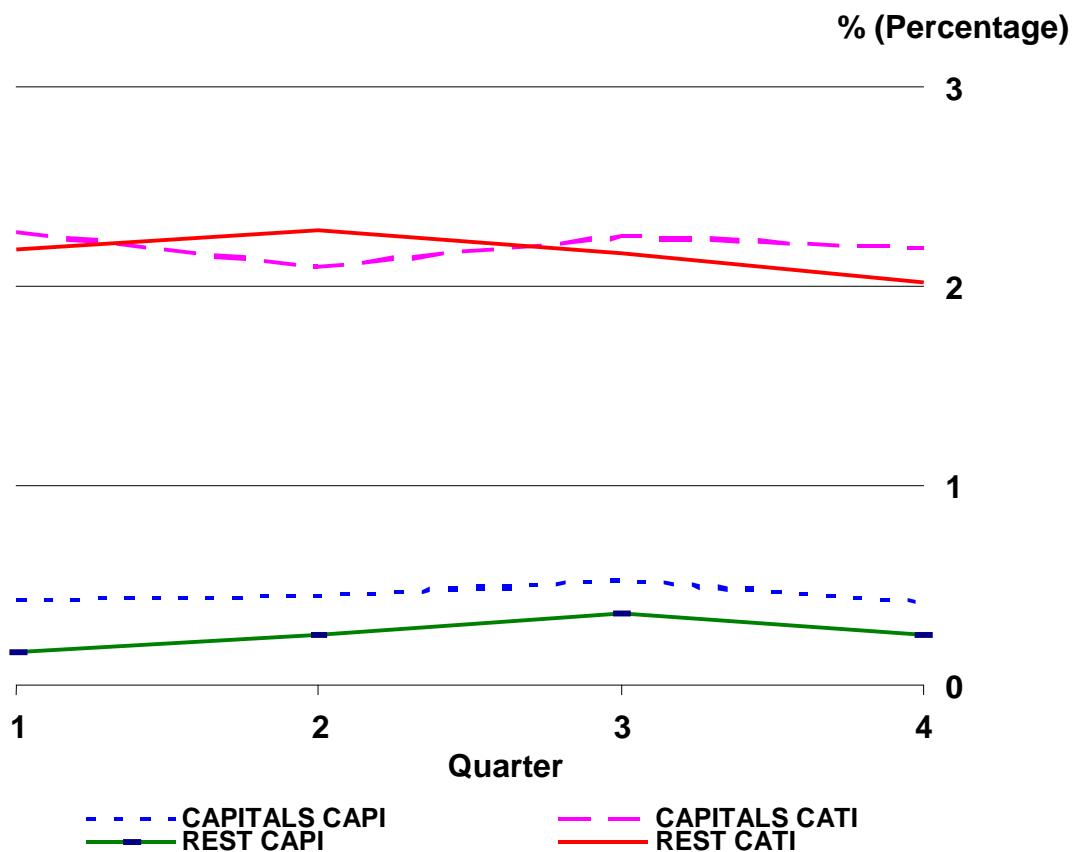

Graph 1 shows, at first sight, that the percentages of unavailable dwellings are quite a bit higher with CATI than with CAPI, which seems logical since, in CAPI, inaccessibility is due, as has already been mentioned, to adverse climatological

conditions or to the absence of adequate roads to access them, circumstances which, normally, do not involve a high number of cases.

In the case of CAPI, a distinction is made between the first and subsequent interviews, being able to observe that the percentages are lower in the first interview. In the case of CATIM, worth noting the decrease registered in the percentage of unavailable dwellings in the second and mainly in the third quarter of the year.

The percentages of inaccessible dwellings, according to the type of municipality (capitals or the rest) are presented in **graph 2**, where it can be observed that there are no appreciable differences in CAPI, whereas in CATI the percentages of the capitals are quite higher than the percentages of the rest of the municipalities in the second and third quarters.

Graph 2 Inaccessible dwellings

3.2 Failure to update the framework

A dwelling is defined as *unsurveyable* in the EAPS when, at the time of the interview, it is empty, it is a seasonal dwelling, it is intended for purposes other than those of a family residence (other purposes), or it is unlocatable at the address that appears in the selection list. These cases indicate that the framework of the survey contains errors due to not being updated, and therefore, these units may be considered as *erroneous inclusions in the framework*.

Table F.D.0 in the Annex contains a summary of incidences which have taken place, in the four quarters of the year, in the total number of selected dwellings, in other words, including those assigned to CAPI and in those assigned to CATI. The information is broken down into *first and subsequent interviews*, on the one hand, and into *capitals and other municipalities*, on the other. This table, as with F.D.1 and F.D.2, only shows the incumbent dwellings, not including therein the reserve dwellings.

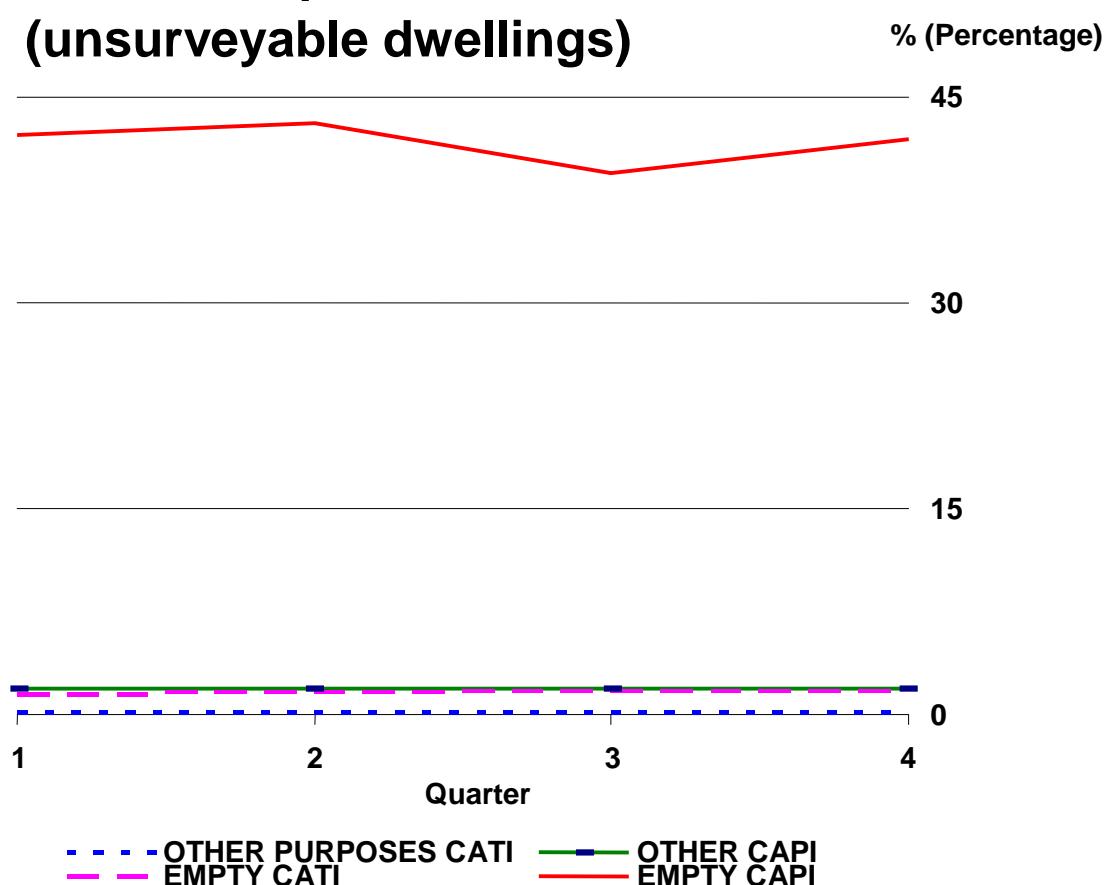

The breakdown of incidences in dwellings assigned to the CAPI method can be seen in table F.D.1 in the Annex, where a distinction is made between provincial *capitals* (stratum 1) and other *municipalities* (strata 2 to 9) and between *first and successive interviews*. In this table, we can observe that the fact that it is out of date is basically due to the high number of *empty* dwellings, regarding which the number corresponding to those *intended for other purposes* and those that are *unreachable*, jointly known as *others* in **graph 3** shown below, is practically insignificant. The total percentage of empty dwellings in CAPI is very stable over the year and only undergoes minimum variations.

In turn, table F.D.2 of the Annex shows the incidences of dwellings assigned to the CATI method, and it can also be seen that the failure to update the framework is primarily due to the empty dwellings, which are equally insignificant regarding those *intended for other purposes* as a whole (in CATI there are no unreachable dwellings). We observe that the percentage of empty dwellings remains quite invariable during the year, around 1.8%. This table only draws a distinction between capitals and the rest of the municipalities, since all of the dwellings assigned to CATI are in subsequent interviews.

Graph 3 shows the percentages of unsurveyable dwellings in CATI and in CAPI throughout the year; we can observe the large difference between the percentages of empty dwellings in CAPI and in CATI. This difference may be explained by the fact that, for the majority of the empty dwellings, there is no telephone number, and therefore, once they have been detected in the first interview, they must remain assigned to CAPI rather than passing to CATI.

Graph 3

Failure to update the framework (unsurveyable dwellings)

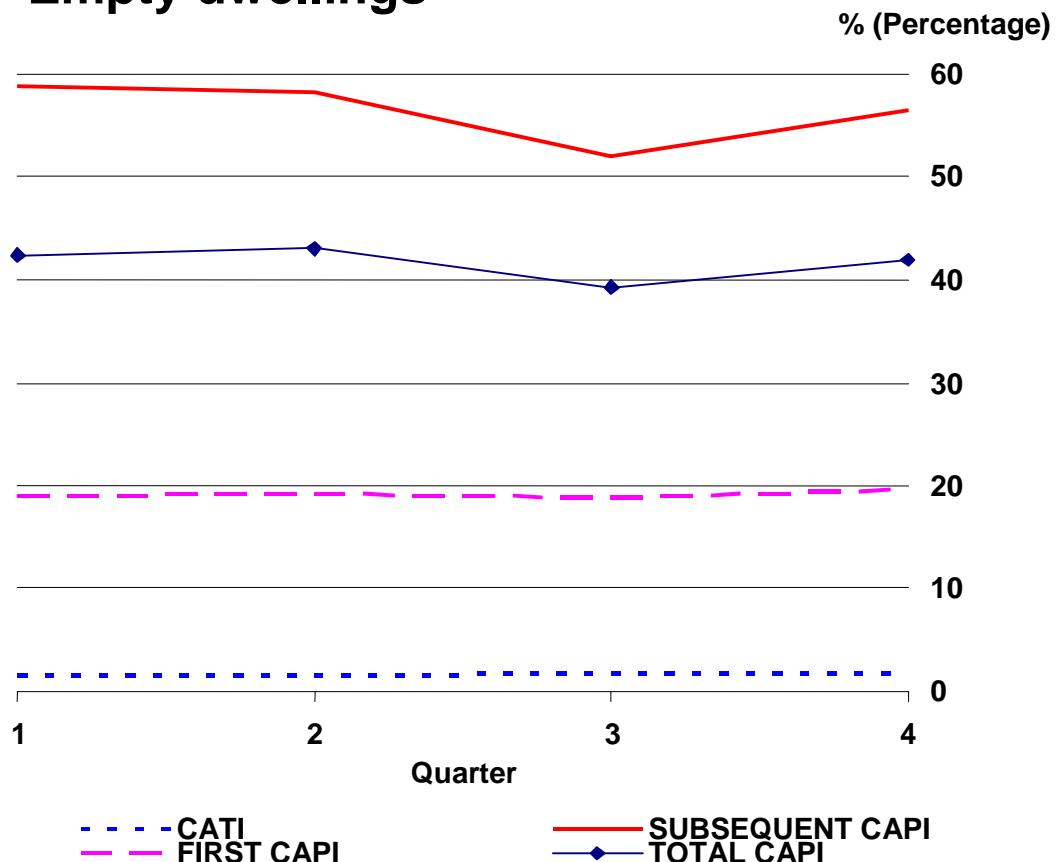

In turn, empty dwellings are visited (or contacted by telephone where possible) all of the quarters, in case they come to be inhabited; therefore the highest percentages for empty dwellings in subsequent interviews in CAPI (see table F.D.1), standing around 58% of the selected dwellings, whereas in the first interview, they fluctuate around 20%, as can be verified in **graph 4**.

Graph 4

Failure to update the framework

Empty dwellings

In turn, **graph 5** shows empty dwellings in CATI and in CAPI, differentiating in both cases between capitals and the rest of the municipalities. It can be seen that both in CATI and in CAPI, the percentages of empty dwellings are higher in the other municipalities than in the capitals, although in CAPI the differences are much greater than in CATI, where they are minimal.

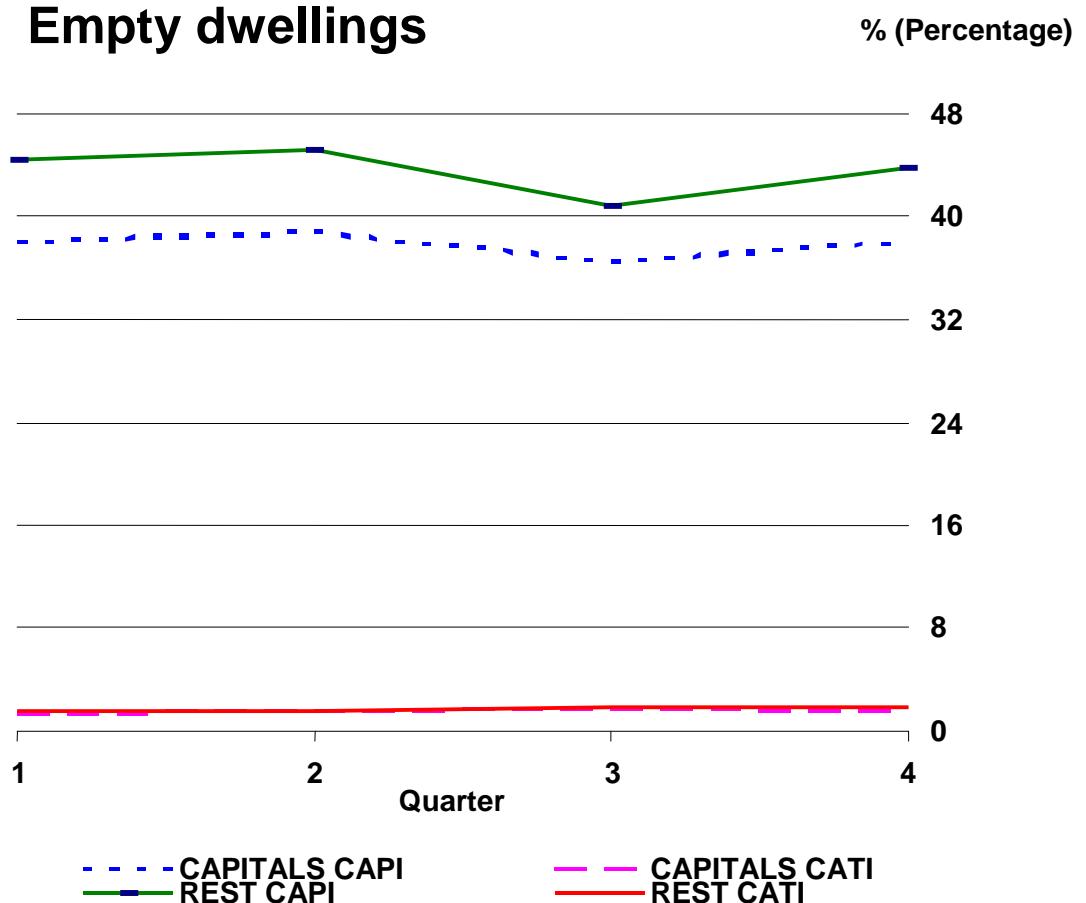

In addition to the periodic updating of likelihood of the section sample, and in order to keep the sample updated, in each quarter of the survey, the framework of dwellings of one sixth of the sample sections is updated, according to the established rotation shifts mentioned above.

This updating consists of going through the section in order to register newly-constructed buildings and dwellings, visit empty dwellings and commercial premises, in case any of them have become inhabited dwellings, and verify the section's limits. Conversely, the inhabited dwellings are not visited to check on whether they are still inhabited, and therefore, it is possible for the percentage of empty dwellings of the framework to increase gradually over the years.

Graph 5

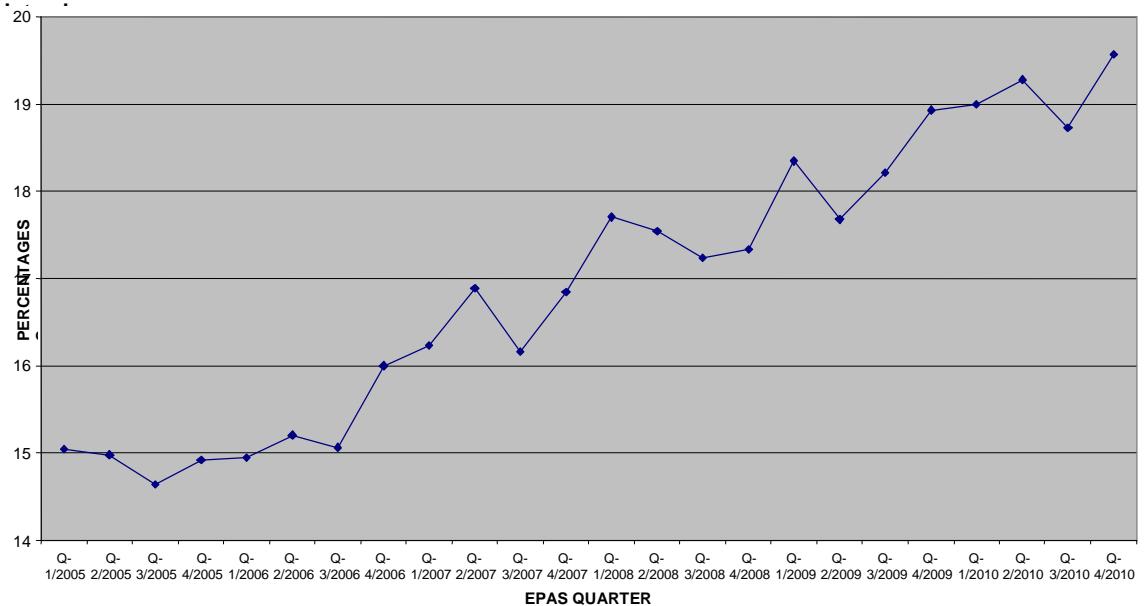

Failure to update the framework

Empty dwellings

Graph 6 represents the evolution over time of the percentage of empty dwellings regarding the owner occupier dwellings selected. The variation from the first quarter of 2005 has been represented; this was when collection by CAPI and CATI methods commenced to date only considering the data from dwellings assigned to CAPI who were in the first interview, with the purpose of obtaining more representative results. This is done in this way as empty dwellings detected in the first interview are visited again in successive interviews to see whether they have changed situation, for which reason the immense majority of empty dwellings in these interviews are those which had been classified as such in the first interview. The aforementioned may be observed: the percentage of empty dwellings increases over time.

Graph 6. Evolution of the percentage of empty dwellings, as compared with the incumbent dwellings. CAPI 1st

Within the quality assessment programme, in order to detect mistakes made in the process of updating the sample sections, a sample of 200 sections per year has been selected to go through it a second time (50 in each quarter), of which, it has only been possible to study 128, due to different incidences arising in the organisation of the fieldwork.

The *Unsurveyable* dwellings, according to the original interview (O.I.), and the *surveyable* dwellings, according to the repeat interview (R.I.) (are actually omitted in the framework, and therefore they are unlikely to be part of the sample).

The results by stratum, expressed as a percentage of the surveyable dwellings from the sections selected for the assessment, are shown in **table 2**.

It is observed that the percentage of dwellings omitted in the framework for the total of the strata is plenty small, only 1.32%, which allows us to state that the form in which the updates are performed is reasonably good.

Beyond the quality evaluation in the process of updating sections, the information on surveyable dwellings according to E.R. and not surveyable according to E.O., and vice versa, in the sample of sections selected to interview in E.R. can be seen in chapter 4 of this study.

2. Omissions of dwellings in the framework

Stratum	Sections updated in R.I.	Surveyable dwellings in O.I.	Dwellings that are unsurveyable in O.I. and surveyable in R.I. (omissions)	
			Total	Porcentaje
1	35	23.505	391	1,66
2	4	2.298	44	1,91
3	2	1.224	99	8,09
4	3	1.577	36	2,28
5	7	4.299	133	3,09
6	11	8.088	83	1,03
7	7	6.163	49	0,80
8	7	5.151	255	4,95
9	9	4.983	27	0,54
Total	85	57.288	1.117	1,95

3.3 Non-response

Non-response in a dwelling belonging to the group being studied may be due to the **absence** of its occupants, or to their **refusal** to participate in the survey.

The percentages of these two types of incidence are shown in tables F.D.1 and F.D. 2 of the Annex, these being calculated with regard to the total for surveyable dwellings, as can be seen. **Graph 7** similarly shows the evolution, throughout the year, of the two components of non-response, with a distinction being made between CATI and CAPI.

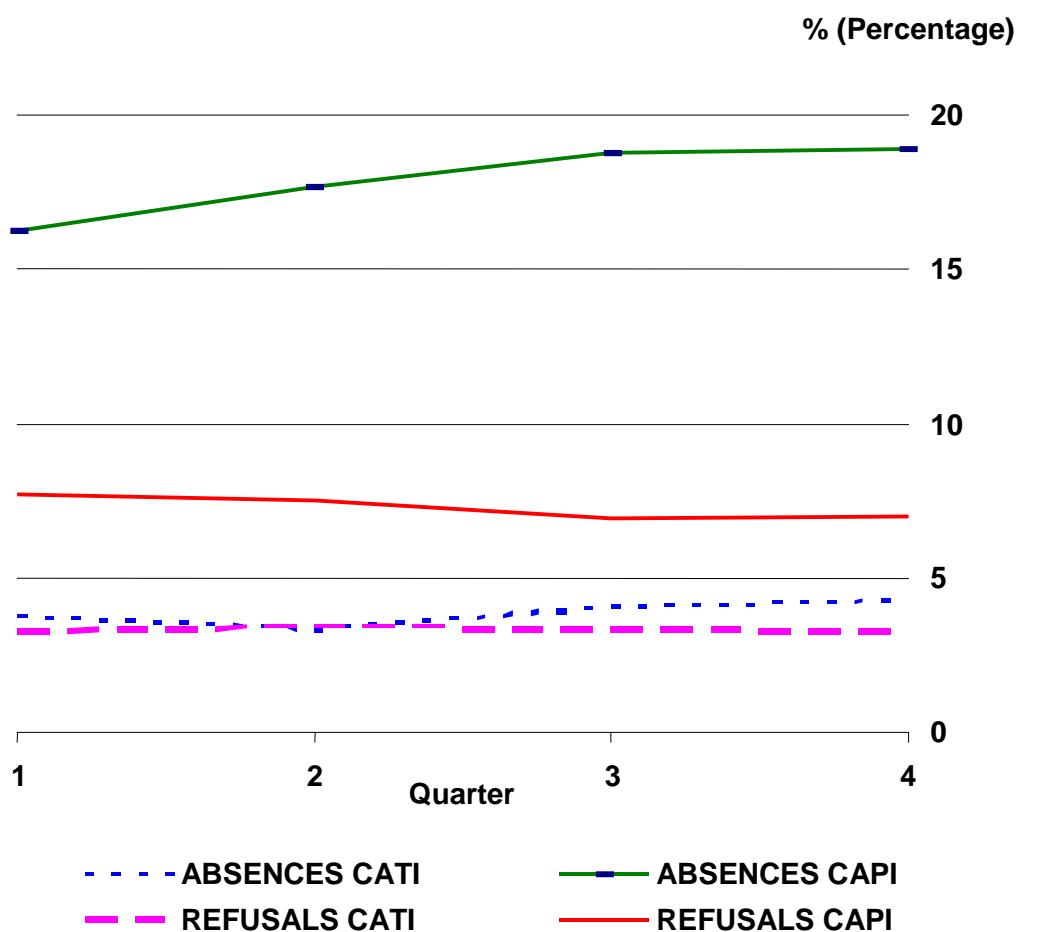

We observe that with CAPI, we can observe that the percentages of absences are significantly higher than those corresponding to refusals, since whereas the former stand, on average, at around 19.4%, the latter stand at around 7.5 per cent. Regarding CATI, the percentages of absences are also higher than those of refusals, but the differences between them are much lower than those registered in CAPI.

If we compare the percentages of absences in CATI and in CAPI, we can see that they are much higher with the latter collection method. This seems reasonable if we take into account the fact that it is easier to contact a resident in the dwelling, during the day, by telephone rather than by a personal visit, particularly in dwellings in which all residents work away from home.

Regarding refusals, it can be observed that the percentages are likewise higher in CAPI than in CATI, although in this case, the differences are smaller. This is due to the fact that the dwellings in CATI, for the most part, have participated previously, on at least one occasion.

Graph 7

Non-response

3.3.1. REFUSALS

A refusal occurs when all persons aged 16 years old or over, who are resident in a dwelling, refuse to participate in the survey.

If the refusal takes place in the first quarter of participation, the dwelling is replaced at random by a reserve dwelling from the same section, until a group is found that does participate, or is absent or inaccessible. When a refusal occurs in the second or subsequent quarters of participation, no replacement is made and an imputation is carried out with the data for the previous quarter, with the dwellings revisited during the remaining quarters during which they remain in the survey (up to six), in case they change their stance or in case of changes in the human group. This imputation is only carried out the first time there is a refusal; if this persists into the following quarters, it entails a sample loss.

Therefore, refusals in subsequent interviews are not, by and large, first-time refusals, but rather *ongoing* refusals from previous interviews.

In tables F.D.1 and F.D.2 of the annex we can see the percentage refusals obtained, both in CAPI and CATI.

When refusal occurs for *the first time*, a *questionnaire of refusals* is completed in order to collect some of the data for assessing possible biases, which may arise from non-response. This data is: sex, age and relationship with the dwelling reference person who refuses to participate in the survey, and age, sex, nationality, educational level, relationship with economic activity, occupation and branch of activity for the reference person.

In case the human group refuses to provide this information (*direct information*), information taken from previous interviews is queried (where there was previous cooperation) or, lastly, the Municipal Register of Inhabitants. **Chart 3** shows the origin of the information for refusal questionnaires in the four quarters, for the total of these, and making a distinction between CATI and CAPI.

Focusing on the quarterly average, it can be observed that, in the case of CAPI, most (78.5% on average) of the data from the refusal questionnaires is obtained by *direct information*, whereas in CATI, it is the *information from previous interviews* that which constitutes the main source of information, thus obtaining 92.4% of the data.

The fact that in CATI, the majority of the information is obtained from previous interview data makes sense, since this collection is only used in subsequent interviews, once the dwellings have already participated, in general, on at least one occasion, except in the cases of change in the human group or absence in the first interview.

If we correlate the average quarterly number of first-time refusals in table 3 with the average quarterly number of total refusals (obtained by adding the refusals in tables F.D.1 and F.D.2 in the Annex), we obtain the average quarterly number of *first-time refusals* standing at 59.5% of the total number of refusals.

3. Origin of the information from the questionnaires on refusals for the first time

As mentioned previously, the dwellings comprising the sample remain in it for six consecutive quarters, renewing one-sixth of the same each quarter, according to established rotation shifts.

Chart 4 shows the distribution of *refusals for the first time*, according to the number of *effective interviews* of the human group in which they have occurred. This presents both the total of the refusals for the first time and the breakdown thereof, depending on the collection method used, whether it be CAPI or CATI.

4. Refusals for the first time, according to the interview number of the human group. Totals

Interview number	Quarter

- Fourth interview	14	1.3	28	2.7	16	1.5	32	3.1	23	2.1		
- Fifth interview	19	1.7	17	1.7	22	2.1	12	1.2	18	1.7		
- Sixth interview	14	1.3	16	1.6	10	0.9	12	1.2	13	1.2		

It can be observed that, with CAPI, on average, almost 88% of families that refuse to participate in the survey for the first time, do so in the first interview, with 95% of them doing so in one of the first three interviews.

As mentioned previously, the CATI method is used in those dwellings corresponding to the sections which, according to the rotation shift, correspond to the second or subsequent interviews, and therefore, the refusals for the first time that appear in the CATI section of table 5 in the first interview must correspond to dwellings in which there has been a change in the human group or to dwellings which, in the previous quarter or quarters, were empty, inaccessible or intended for other purposes, or in which the human group was absent.

Chart 4 shows that, with CATI, 30% of families that have refused for the first time to participate in the survey have done so in the second interview, with 69% of them doing so between the second and the fourth interviews.

If we compare figures for refusals in the first CAPI interview in table 4 and in table F.D.1, it can be observed that there is a considerable difference; between them. The data in table F.D.1 corresponds to refusals of dwellings in which, due to rotation shift, are in the first interview, whereas in table 4, refusals for the first time are presented, including those occurring in dwellings that are in both the first interview and subsequent interviews (if the refusal takes place following one or more previous collaborations, absences or unsurveyable or inaccessible dwellings, or if there has been a change in the human group), the figures are therefore not comparable.

Some features of the reference person of the dwellings that refused to participate for the first time in the EAPS are presented in **tables F.D.3.1 to F.D.3.6**. It can be observed that, in general, the percentage of cases in which it was not possible to obtain data from the refusal questionnaire (*no data recorded*) is high, particularly for the characteristics *relationship with economic activity* and *educational level*, for which it stands at 58 and 54%, respectively. Such high non-response values subtract validity from any conclusions that could be obtained from these tables; nevertheless, the end of table **F.D.3.3** includes the percentage distribution of family dwellings, according to the relationship with economic activity of the reference person, obtained from EAPS 2011 (average for the four quarters), and by comparing this distribution, which serves as a reference, with that from the quarterly average for refusals, it could be said that first-time refusals are concentrated in dwellings where the reference person is in *another situation* as regards economic activity, in other words, in that they are neither employed nor unemployed.

In the remaining tables, it has not been possible to obtain reference distributions, since they are not available among the EAPS information.

In turn, **table F.D.3.7** presents the distribution of refusals for the first time in accordance with the number of persons in the dwelling. In the final column of this table, it has been possible to include, as in table F.D.3.3, the percentage distribution of family dwellings, by number of persons, obtained from EAPS 2011 (average for the four quarters). If we compare this distribution with that for the quarterly average of refusals, we may reach the conclusion that refusals for the first time are concentrated primarily in one-person and two-person dwellings.

Lastly, **table 5** presents the distribution of the refusals for the first time, according to the reason expressed by the person refusing the interview, distinguishing between CATI and CAPI. It can be observed that both in dwellings assigned to CATI and those assigned to CAPI, the highest percentage of first time refusals corresponds to the modality *does not state reason*, which attains 27.5% in CATI and 29% in CAPI.

In CATI the second most important reason corresponds to *lack of interest* (26.7%), while in CAPI this is *death or illness* (23.4%).

5. Refusals for the first time, according to the reason expressed by the person refusing to participate in the interview

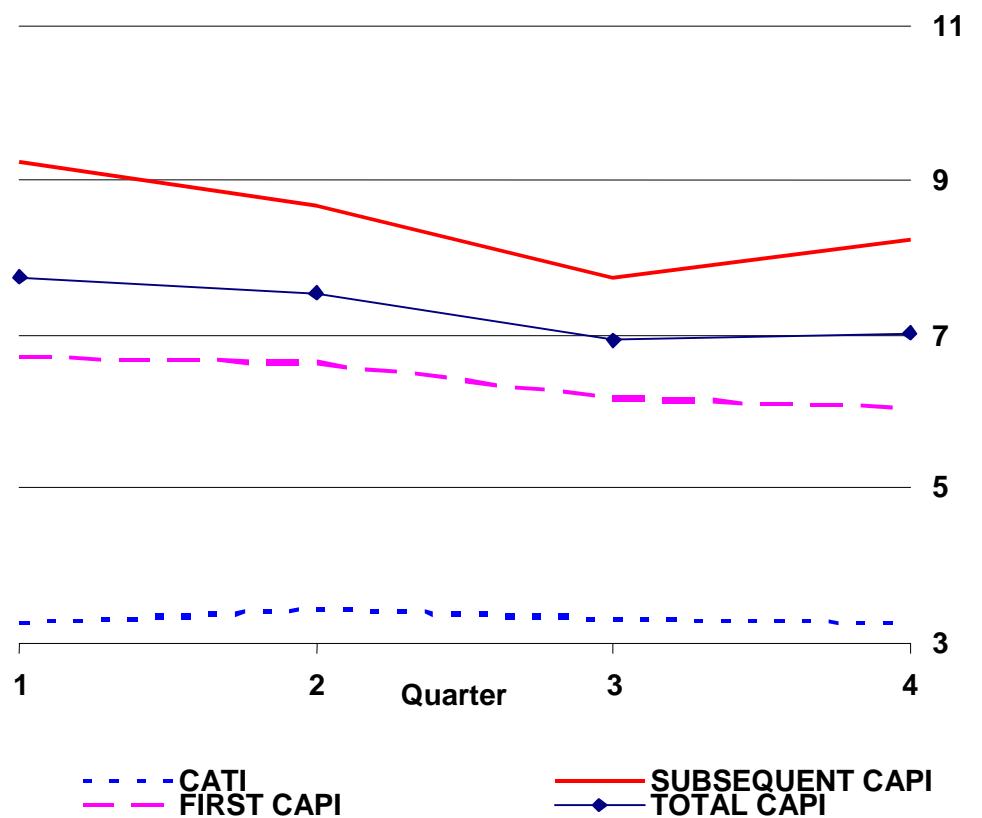

Graph 8 represents the percentages of refusals for CATI and for CAPI in the four quarters, with a distinction being made for the latter method between the first and subsequent interviews

Firstly, please note that the percentages of refusals are significantly higher in CAPI than in CATI, as we have already mentioned. Secondly, and on the subject of CAPI, we can see that refusals are relatively more numerous in the subsequent interviews than in the first interview. This is due to the fact that, as with the empty dwellings, refusals are revisited in the remaining participation quarters in case there are changes, either in the attitude of the human group with regard to the survey, or in the human group itself; therefore refusals in subsequent interviews are, for the most part, refusals continuing from previous quarters.

Graph 8

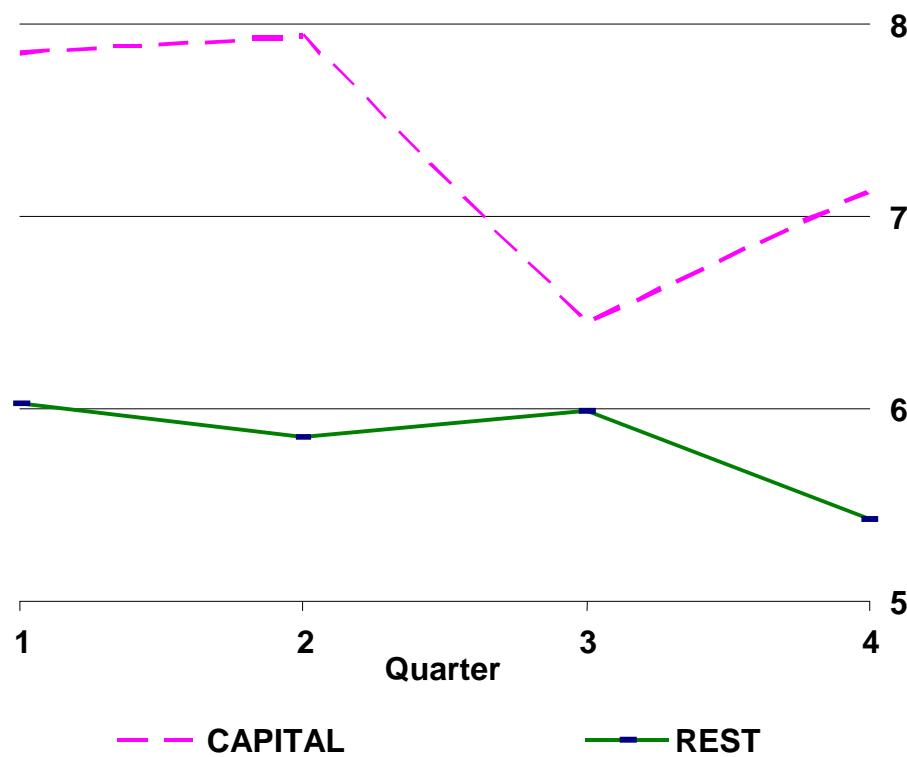

Non-response Refusals

% (Percentage)

The percentages of refusals, depending on the type of municipality, are represented, for dwellings in CAPI in the first interview, in **graph 9**. We observe that percentage of refusals are, over the four quarters, highest in provincial capitals than in the remaining municipalities.

Graph 9
Non-response
Refusals in CAPI 1st interview % (Percentage)

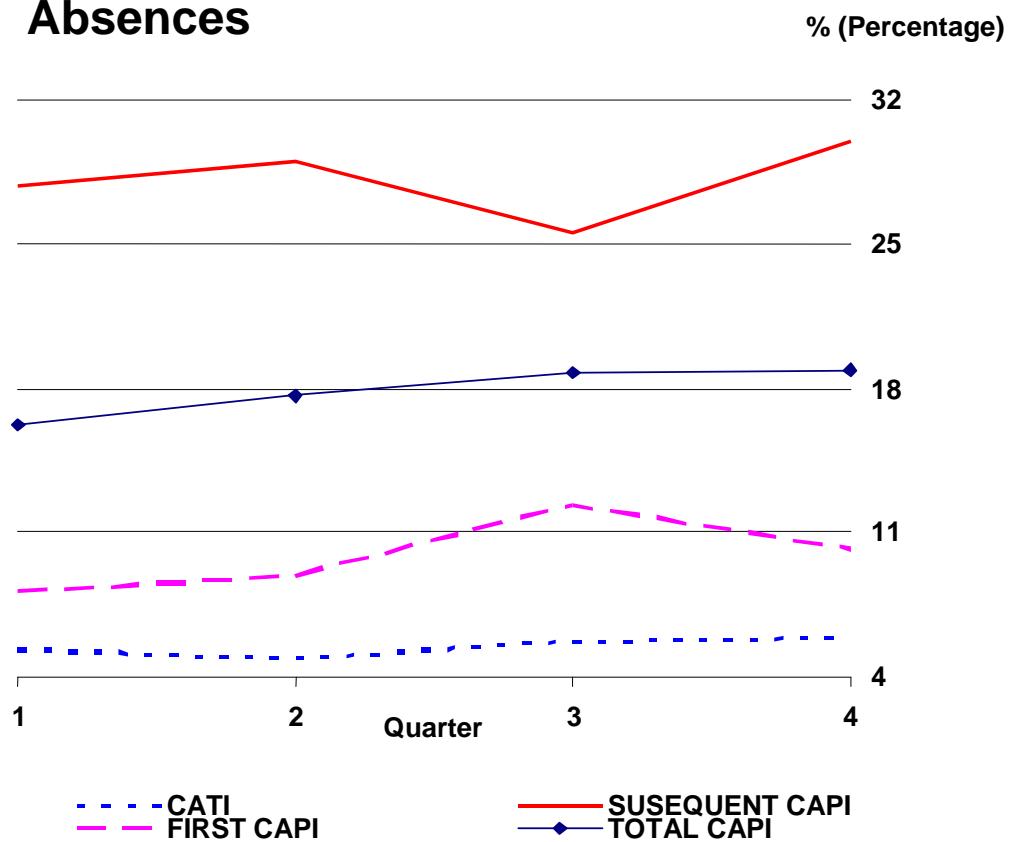

3.3.2. ABSENCES

Absence in a dwelling occurs when no person from the human group occupying it is present, in the subsequent visits that the interviewer makes to the dwelling, during the time remaining in the section.

In case of the temporary absence of the occupants of the dwelling, the interviewer repeats her/his visits or telephone calls in order to try to obtain the information, as long as the working calendar allows. If, despite all attempts, they are unable to contact any of them, the dwelling is then considered to be definitively absent, and s/he again tries to contact it the following quarter.

Graph 10

Non-response Absences

Graph 10 reflects the percentages of absences for CATI and CAPI in the four quarters, distinguishing for the latter method between the first and the subsequent interviews.

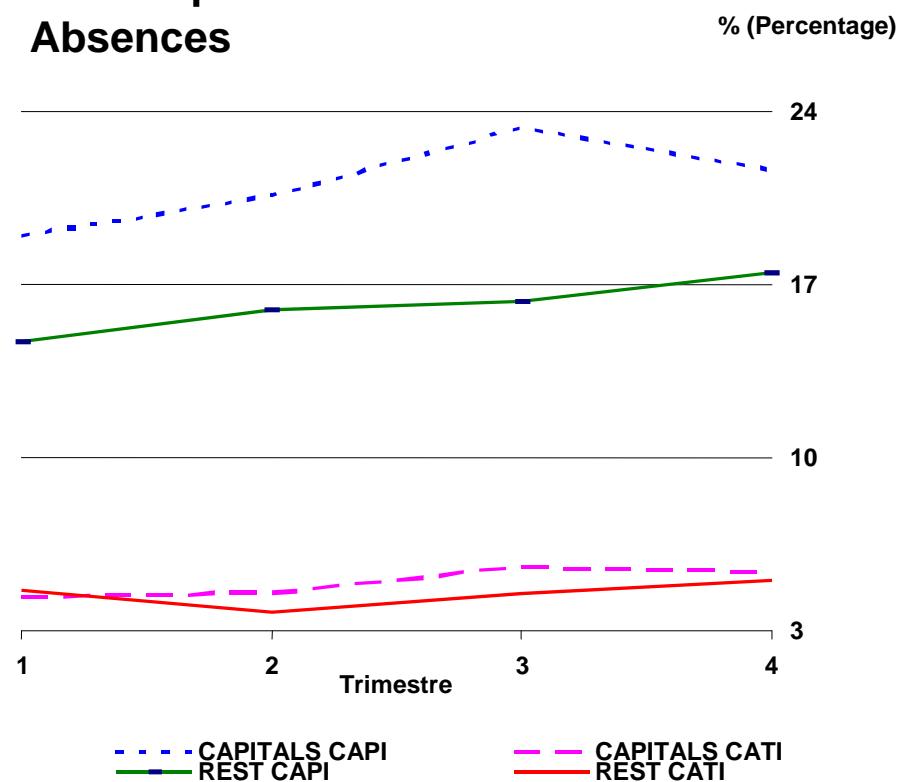

Firstly, the percentages of absences are significantly higher in CAPI than in CATI, as mentioned previously. Secondly, and with reference to CAPI, we can see that the absences are much more numerous, in relative terms, in the subsequent interviews than in the first interview. This is due, firstly, to the fact that, as with the refusals, there are absences continuing from one quarter to the next, and secondly, to the fact that the number of surveyable dwellings is much lower, as compared with the number of selected dwellings, in subsequent interviews than in the first interview.

Finally, we observe that whilst in CATI the percentage of absences stays quite stable over the year, in CAPI we note more ups and downs in this.

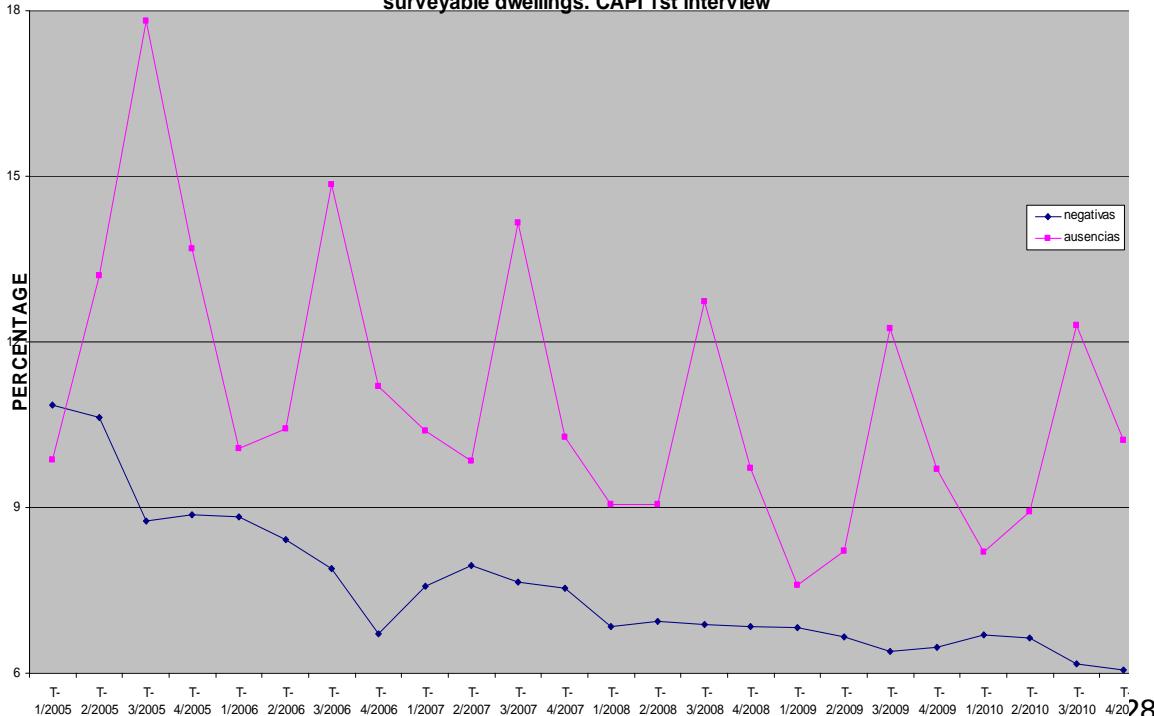

The percentages of absences, depending on the type of municipality, are represented, for CATI and for CAPI, in **graph 11**. We observe that in CATI percentages are very similar, in general they are somewhat higher in the province capitals. In CAPI, the percentages of absences are always higher in the

capitals than in the remaining municipalities, yielding an average difference of around six percentage points.

Graph 11 Non-response Absences

Graph 12. Rates of refusals and absences, with regard to surveyable dwellings. CAPI 1st interview

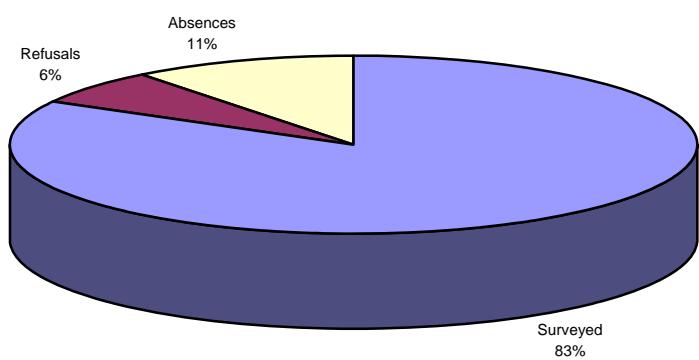

Graph 12 represents the time evolution of the rates of refusals and absences, from the first quarter of 2005 to the fourth quarter of 2011, in the dwellings that have been included in CAPI and that were in their first interview. The reason for considering only these dwellings, excluding those in subsequent interviews, is to obtain more representative results, on not considering the refusals and absences carried over from previous quarters in the latter interviews. In turn, the reason for beginning the graphical representation of the data in the first quarter of 2005 is that it was in this period when the collection, differentiated by CAPI and CATI method, was implemented.

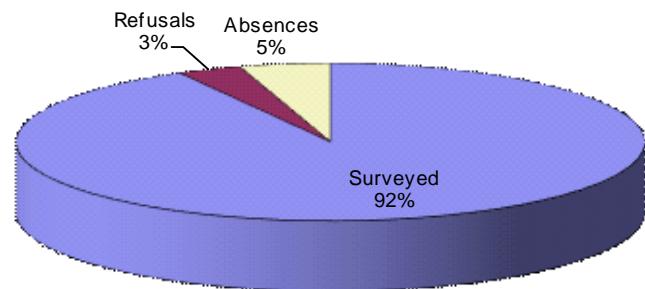

It can be observed that both rates (percentage refusals and absences regarding surveyable dwellings), tend to decrease, although, in 2011, they have slightly recovered as compared to values in 2010. In the case of absences, we can see the increases that take place in the third quarter of each year, coinciding with the longest family holiday period.

The graphical representation of the percentage distribution of the surveyable dwellings, considering the average of the data of the four quarters of the year, in CAPI and in CATI, may be viewed in **graphs 13 and 14**, respectively.

Graph 13.

Quarterly average

3.4 Incidences in the sample in the different Autonomous Communities

Charts 6.1.1 to 6.4.2 present the **incidences** registered in the selected dwellings for the four quarters of the year, by Autonomous Community and according to the collection method used. The percentages of surveyed dwellings, refusals and absences have been calculated with regard to the total for surveyable dwellings, instead of regarding the total number of selected dwellings.

Considering the average values of the four quarters, contained in tables 6.5.1 and 6.5.2, in **the dwellings assigned to CAPI** (see **table 6.5.1**) we can see, firstly, that the percentages of unavailable dwellings are very small. In terms of the failure to update the framework, of particular note is Comunidad de Madrid, with 31%, the Community with the lowest average quarterly percentage for unsurveyable dwellings, whereas at the other extreme, Aragón and Castilla-La Mancha stand out with an average percentage for unsurveyable dwellings of 52.9%. These very high percentages of non-surveyable dwellings are because, as mentioned, of the fact that empty dwellings are visited every quarter in case they became inhabited and the way in which the surveys are updated (see section 3.2).

If we then study non-response, including refusals plus absences, we can see that Canarias is the Community with the highest quarterly average, reaching a value of 43.6 percent. The least non-response corresponds to Murcia, whose quarterly average stands at 16.1%.

If we break non-response down into its components, we can observe that the highest quarterly average percentage of refusals corresponds to Ceuta, with 14.5%. The Community with the fewest refusals is Cantabria, whose quarterly average stands at 1.2%.

In terms of absences, Canarias, with an average of 35%, is the Community with the highest percentage. At the other extreme is Cataluña, with a value of 5.5%, the Community with the lowest percentage.

As regards **dwellings** that were **assigned to CATI**, and likewise considering the average values for the four quarters (see **table 6.5.2**), we can observe that the percentages of unavailable dwellings are greater than in CAPI, with Melilla reaching the highest value, at 7.3%. This fact is explained by the different meaning of *inaccessible dwelling* in CATI and in CAPI, as already mentioned in sections 3 and 3.1. Also regarding the unsurveyable dwellings, worth noting is Melilla, with 0.4%, as the Community with the lowest average quarterly percentage. At the opposite end of the spectrum, Comunidad Valenciana stands out with 4%.

If we study non-response, we can see that Comunidad de Madrid is the Community with the highest quarterly average, standing at 13.5 percent. The least non-response corresponds to Galicia, whose quarterly average stands at 5.9%.

Breaking down the lack of response into its components, we can see that with regard to refusals País Vasco is notable with the highest value, 9.1%. Among the Communities with the fewest refusals, Cataluña, whose quarterly average stands at 1.9%, is of particular note.

In terms of absences, Illes Balears, with an average of 9.8%, is the Community with the highest percentage. At the other extreme are Extremadura and Navarra, registering percentages around 3%, the Communities with the lowest relative number of absences.

Lastly, tables 6.1.T to 6.4.T show the incidences occurring in the four quarters of the year, by Autonomous Community, for the complete sample of incumbent selected dwellings (that is, for the whole of CAPI + CATI). Table 6.5.T includes the average values for the four quarters of the year.

Considering the values of this last table, we can observe that, firstly, the percentages of inaccessible dwellings are small, with lowest corresponding to Castilla y León (0.9 percent), and the highest corresponding to Melilla, with 3.2 percent. In terms of the failure to update the framework, of particular note is Comunidad de Madrid, with 9.8%, the Community with the lowest average quarterly percentage for unsurveyable dwellings, whereas at the other extreme, Extremadura stands out with an average percentage for unsurveyable dwellings of 27.8%.

If we then study non-response, including refusals plus absences, we can see that Melilla reaches the highest quarterly average, reaching a value of nearly 25.8%. The least non-response corresponds to Comunidad Valenciana and Galicia, whose quarterly average stands around 9.8%.

If we break non-response down into its components, we can observe that the highest quarterly average percentage of refusals corresponds to País Vasco, with 9.1%. Among the Communities with the fewest refusals, Cantabria, whose quarterly average stands at 1.9 percent, is of particular note.

In terms of absences, Melilla, with an average of 20 percent, has recorded the highest percentage. At the other extreme are Galicia and Murcia, with 6%, the communities with the lowest percentage.

Melilla	100,00	2,51	26,41	71,08	100,00	76,57	7,56	15,87	23,43		

4. Assessment survey

The EPA quality evaluation survey, which the INE has been performing since 1971, has a twofold aim:

- To monitor the work of the interviewers who are involved in the EAPS.
- To assess the quality of the results.

To this end, we have followed a mathematical model compiled by the Census Office of the United States, due to Hansen, Hurwitz and Bershad, based on the *repeat interview*. The operating procedure, very simple, consists of repeating the interviews in a sample of the dwellings selected for the original survey. Subsequently, the data obtained on both occasions is compared, for the purpose of studying the inconsistencies, and quantifying the errors, through the application of different quality indices. The model of Hansen, Hurwitz and Bershad assumes that, in the second interview, or *repeat interview*, we obtain the true values of the characteristics being studied. Although in practice it is difficult to prove whether or not this objective has been reached, the data from the repeated interview, obtained with more means and better-prepared interviewers, is assumed to be of a superior quality than the primitive data, and will enable basing on it all of the calculations of errors and biases.

The comparison of the results obtained from the original interview (O.I.) with those obtained in the repeat interview (R.I.) enables assessing two large types of error that are not sampling errors, which affect the quality of the results:

- a) Coverage errors**, produced by the erroneous omission or inclusion of units in the original survey.
- b) Content errors**, which affect the characteristics studied of the surveyable persons.

The fieldwork is carried out by specialised interviewers who conduct the repeat interview at most fifteen days after the original interview, with the data from both interviews referring to the same period of time.

As is well-known, the EAPS the information collection method differs according to whether the dwellings are in a first or subsequent interviews, with CAPI used in dwellings that are in the first interview and primarily CATI in dwellings that are in the second or subsequent interviews.

Due to the desire to use the same information collection method used in the EAPS in the assessment survey, we have opted for using a CAPI system in the repeat interview, foregoing the CATI system due to its greater complexity of implementation. Taking into account this set of circumstances, the sample of sections to be researched in the assessment survey is selected from among the EAPS sections in the first interview, and therefore the results of this interview will be applicable to dwellings in the first interview. Nevertheless, it is to be expected that the behaviour of dwellings in the second and subsequent interviews do not show large differences as compared with those in the first.

The evaluation survey is quarterly, that is, each quarter we select a sample of sections to investigate. With each quarterly sample, the aim is to inspect work carried out in all of the Autonomous Communities, except Ceuta and Melilla, studying, wherever possible, at least one section from each province.

For the quarterly selection of the sample, four zones have been created taking all the Autonomous Communities, except Ceuta and Melilla, grouping several Communities into each, such that each Community is included in one, and only one, of these zones. In order to complete up to thirteen (the number of weeks in each quarter), previous zones have been repeated twice, and one of them once again, in other words, one zone is repeated three times.

Lastly, a zone is assigned by means of a random procedure to each week in the quarter, with visits each week to the sections in the provinces of the Autonomous Communities of the zone corresponding to this.

Using this method, between 140 and 150 sections are selected each quarter. In these sections, the interview is repeated in half of the O.I. incumbent dwellings, with even- or odd-numbered dwellings selected at random, the number of studied dwellings thereby standing at between 1,400 and 1,500, representing approximately 12 percent of the dwellings from the first EAPS interview (2 percent of the total EAPS sample).

In the repeat interview, a slightly reduced questionnaire is used (in other words, with a few less questions) as compared with the short EAPS questionnaire (the one used in interviews 1 to 5).

Despite the quarterly nature of the assessment survey, the results are to be given for the whole year, since, being independent quarterly samples, it is possible to group the data.

Chart 7 considers the distribution of incidences in dwellings selected for the assessment survey (R.I.) sample.

7. Incidences in the sample of R.I.

Selected dwellings	Nº	%
Total	2,564	100.00
Unavailable	1	0.04
Unsurveyable	543	21.18
Surveyable	2,020	78.78
- Surveyed	1,608	62.71
- Non-response	412	16.07

In order to compare non-response (refusals + absences) in O.I. and in R.I., **table 8** presents its percent distributions in both interviews. O.I. data has been obtained by calculating the average of the figures corresponding to CAPI for the first interview in the four quarters of the year. It can be observed that the percentage of non-response is much greater in R.I. than in O.I. (17.9% as compared with 16.5%), as is usual, although aforementioned difference has been decreasing considerably over the years, due mainly to absences, which

have the greatest incidence in non-response. The difference in the percentage of absences between O.I. and R.I. is three tenths and a half. Regarding this fact, it is appropriate to emphasize that the R.I. agents conduct their interviews with greater time limitations, given that as they do not reside in the province, they spend less time in the section.

8. Percentage distribution of surveyable dwellings in O.I. and in R.I.

Dwellings	E.O.	E.R.
surveyable dwellings	100.00	100.00
- Surveyed	83.70	79.60
- Non-response	16.30	20.40
- Refusals	6.39	4.95
- Absences	9.91	15.45

Table 9 includes the coincidences and discrepancies in terms of the coverage of dwellings, between O.I. and R.I., in absolute and percent values. From the analysis thereof, it may be concluded that there is a high degree of agreement between both interviews, which is reflected in the gross difference (error percentage indicator), with a value of 0.6%.

9. Errors in the coverage of dwellings

	Nº	Percentage
Surveyable/unsurveyable dwellings in O.I. and in R.I.	2,563	100.00
Surveyable in O.I. and in R.I.	2,020	78.81
Surveyable in O.I. but not in R.I.(1)	13	0.51
Surveyable in R.I. but not in O.I.(2)	0	0.00
Unsurveyable in both O.I. and R.I.	530	20.68
Net difference (1) - (2)	13	0.51
Gross difference (1) + (2)	13	0.51

In the dwellings surveyed in R.I., it is generally not possible to use all of the information to assess the content errors, given that some of these dwellings have not been surveyed in O.I., due to the different causes included in **table 10**.

10. Incidences in O.I. in the dwellings that were only surveyed in R.I.

	Total	Percentage
Selected	2,564	100.00
Surveyed in R.I. and in O.I.	1,607	62.68
Surveyed only in R.I.	1	0.04
- Refusals in O.I.	0	0.00
- Absences in O.I.	1	0.04
- Unavailable in O.I.	0	0.00
-Unsurveivable in O.I.	0	0.00

The questionnaires that are processed electronically, and that allow for carrying out the analysis of the coverage errors of persons and of the content errors in the different characteristics of the survey, are only those corresponding to the dwellings whose occupants have been interviewed in both the R.I. and the O.I.

Moving on, the INE is concerned about obtaining data from the best possible source of information. Thus, in the APS, data on the persons inhabiting the dwelling is requested from the reference person, and in any case, from an adult residing there, with no information obtained in those dwellings which do not comply with this requirement.

Chart 11 presents the data regarding the identity of the informant, obtained in the dwellings in which the two interviews were conducted. In approximately 73.4% of the O.I. dwellings, the data was obtained from the reference person, whereas in the R.I. dwellings, this percentage stands near 68.3%. The information was provided by the same person in the two interviews in almost 84% of the dwellings.

The fact that the number of dwellings interviewed in E.O. and in E.R., which appears in tables 10 and 11, in general does not coincide is because of the use of different sources to obtain these. Chart 10 is obtained from summarising the report files collected in the field, whereas the data in table 11 is obtained once the R.I. and the O.I. questionnaires have been electronically processed.

11. Identity of the informant in O.I. and in R.I.

Dwellings interviewed

<u>in O.I. and in R.I.</u>	<u>Nº</u>	<u>%</u>
Total	1,639	100.0

Informant in O.I.

- Reference person	1,092	66.6
- Another person	547	33.4

Informant in R.I.

- Reference person	1,171	71.4
- Another person	468	28.6

The same informant

<u>in O.I. and in R.I.</u>	1,300	79.3
----------------------------	-------	------

5. Coverage of persons

Those persons who reside in dwellings in which it has been possible to conduct an interview, both for the original survey and for the assessment survey, are classified into one of the three following classes:

- Comparable persons
- Omitted persons
- Persons erroneously included

Comparable persons are those persons that both the O.I. interviewer and the R.I. interviewer have considered surveyable. Therefore, we have information for these persons information in O.I. and in R.I..

Omitted persons are those persons whose data has been collected by the R.I. interviewer, on considering them surveyable, but for whom information does not exist in the O.I.

Persons erroneously included are those persons who appear in the questionnaire of the original survey, and whom the R.I. agent has not included in the assessment survey, due to not considering them surveyable.

Both the omissions and the erroneous inclusions are considered errors in the coverage of persons, based on the hypothesis that the information of the repeat interview is of a better quality than that of the original interview.

The assessment of the coverage of persons is based solely on the occupants of the *surveyable* dwellings in which the O.I. and the R.I. have been conducted, table 12 shows that such coverage is good.

12. Coverage of persons

16 years old and over

Persons	Nº	%
Interviewed in R.I.	3,714	100.00
-Comparable	3,684	99.19
-Omitted in O.I.(1)	30	0.81
Interviewed in O.I.	3,694	99.46
-Comparable	3,684	99.19
-Erroneously included in O.I.(2)	10	0.27
Net difference (2)-(1)	-20	-0.54
Gross difference (2)+(1)	40	1.08

This table presents the net and gross differences, interpreting the first as an indicator of the bias, and the second as an indicator of the total errors made.

From the analysis of the data, we conclude that the bias is small, as it stands, in absolute values, at 0.33%, whereas the gross difference stands at 0.98%.

Notwithstanding the small number of persons omitted and erroneously included, tables C.P.1 to C.P.6 of the Annex show the distributions of the same by age, sex, marital status and relationship with economic activity.

6. Content errors

6.1 Presentation of results

Content errors are analysed from the information supplied, in the two interviews, by the persons classified as comparable. The O.I. and R.I. questionnaires for these persons are compared using computer procedures, determining to what extent the two data series differ. To facilitate the analysis, two types of table are compiled: coincidence tables and quality indicator tables.

For a characteristic C with K modalities, the coincidence table responds to the following general format:

R.I. <u>O.I..</u>	Total persons	M ₁	M ₂	...	M _j	...	M _k
Total Persons	n	n _{.1}	n _{.2}	...	n _{.j}	...	n _{.k}
M ₁	n _{1.}	n ₁₁	n ₁₂	...	n _{1j}	...	n _{1k}
M ₂	n _{2.}	n ₂₁	n ₂₂	...	n _{2j}	...	n _{2k}
...
...
...
M _i	n _{i.}	n _{i1}	n _{i2}	...	n _{ij}	...	n _{ik}
...
...
...
M _k	n _{k.}	n _{k1}	n _{k2}	...	n _{kj}	...	n _{kk}

n_{ij} represents the number of persons classified in modality M_i according to the R.I., that in the O.I. had been classified in modality M_j.

The main diagonal includes the number of persons classified in the same position in both interviews in each modality.

These tables allow for studying the transfers of population between modalities, due to content errors.

From the coincidence table, we can extract, for each modality M_i of characteristic C, a dual-entry table as shown below:

R.I.	E.O.	With Modality M _i	Without Modality M _i	Total
With Modality M _i		a	b	a + b
Without Modality M _i		c	d	c + d
TOTAL		a + c	b + d	n

where:

- n** the total persons classified in both interviews, with regard to the reference characteristic.
- a** the number of persons classified in modality M_i in both interviews.
- b** the number of persons classified in modality M_i in R.I. and in a different one in O.I.
- c** the number of persons classified in modality M_i in R.I. and in a different one in O.I.
- d** the number of persons not classified in M_i in either of the interviews.

Based on this reduced table, the following quality indicators are defined:

a) Percentage classified identically

$$P.I.C.(M_i) = \frac{a}{a+b} \cdot 100$$

Varies from zero to one hundred. Indicates response stability. Its optimum value, one hundred, expresses that all persons belonging, according to R.I., to modality M_i, are classified in the same way in O.I.

b) Net change index

$$I.C.N.(M_i) = \frac{c-b}{a+b} \cdot 100$$

This may be positive (c>b) or negative (c<b). It measures the response bias of the survey, expressed as a percentage of the number of households belonging to M_i, according to R.I. Given that, for its calculation, it does not consider the different weighting of the data in each stratum, this index can only be interpreted as an indicator of the bias, and not as an estimator.

c) Net rate of difference

$$T.D.N. (M_i) = \frac{c - b}{n} \cdot 100$$

c) Gross change index

$$I.C.B. (M_i) = \frac{c + b}{a + b} \cdot 100$$

It may be non-existent or positive. This is an indicator of the variance of response, expressed as a percentage of the number of households belonging to M_i in the R.I. It serves as a measurement of the errors which have been made in this modality.

e) Gross rate of difference

$$T.D.B. (M_i) = \frac{c + b}{n} \cdot 100$$

From the definition of these indicators, we conclude that, if there are no content errors in a modality, the CPI takes on the value of one hundred, and the two indices and the two rates take on the value of zero.

It is also important to note that a small, or even non-existent, CPI can co-exist with a zero bias. This occurs when the errors cancel each other out and $b=c$. In turn, the I.C.B. can only take on the value of zero if $b=c=0$, that is, if there is no content error.

The **global consistency index** is used to compare the general quality of the different characteristics assessed, which is defined, for a certain characteristic, as:

$$I.C.G. (C) = \frac{\sum_{i=1}^n n_{ii}}{n} \cdot 100$$

6.2 Analysis of the characteristics assessed

We have obtained coincidence tables for the following characteristics (section 4 of the Annex):

a) For the population aged 16 years old and over

- Age
- Marital status
- nationality
- Educational level
- Relationship with economic activity

b) For the economically active population

- Age and sex
- Marital status
- Educational level
- Professional status
- Occupation
- Branch of activity

c) For employed active persons

- Hours worked in the main activity
- Number of hours worked equal to or different than usual
- Reason for weekly working time different than usual
- Time that they have been working in their current job
- Wage earners by type of contract or labour relationship
- Employees with a temporary contract by Public or Private Sector and duration thereof.

d) For unemployed persons

- Sex
- Economic sector
- Time that they have been seeking work

As already mentioned, the fact that quarterly samples are independent enables grouping of data obtained in the four quarters. This, together with the fact that the quarterly samples are small, has led to the conclusion that it was preferable to present data for the entire year, rather than separately for the four quarters, in

order to thus obtain more representative data. Therefore, the data corresponding to the whole of 2011 is presented in the coincidence tables.

The quality indicator tables (see section 5 of the Annex) have only been obtained for the characteristics that present a smaller breakdown:

a) For the population aged 16 years old or over

- Age
- Marital status
- nationality
- Educational level
- Relationship with economic activity

b) For the economically active population

- Professional status
- Occupation
- Branch of activity

c) For employed active persons

- Hours worked in the main activity
- Number of hours worked equal to or different than usual.

6.2.1 AGE, MARITAL STATUS, NATIONALITY AND EDUCATIONAL LEVEL

The coincidence tables obtained for these characteristics and the corresponding quality indicators are presented in tables C.1 to C.4 and I.1 to I.4 of the Annex, respectively.

The *age* characteristic presents, in all its modalities, **very high** percentages identically classified (CPI) as is usual, as in all modalities except one, this is 99% or above. Net change indices, indicators of bias, are very small and gross change indices are also maintained at very small values since the highest is 2.8%.

Regarding *marital status*, the indicators of the modality *separated or divorced* are still the worst, although the improvement in these experienced over the last few years is still maintained; its CPI attains a value of 94.3%. Net change indices are quite small for all modalities even for the modality *separated or divorced*; we observe something similar in the gross change indices as their values are small, as the highest, corresponding to the modality *separated or divorced* attains a value of 8% It is also appropriate to warn that it is in the modality *separated or divorced* where the fewest persons are classified, barely 4% of the total classified.

In the characteristic *nationality*, the primary modality, into which 95% of the total is classified (see table C.3 of the Annex), is *Spanish*. This modality presents the

highest CPI (100%) and very small net and gross change indices. The other two modalities are therefore very minority, especially Spanish and other *as it is the one* which presents the worst indicators with a CPI of 85.7% and a GCI of 23%, indicating a slight improvement as compared with the previous year.

As for level of training, worth noting, as can be verified in table C.4 of the annex, the low number of people classified in the modalities *Doctorate* and *Illiterate*, mainly in the first one, which implies that its indicators will not be very significant.

In table I.4 of the Annex, we can see, without taking into account indicators of the modalities referred above, in view of their lack of quantitative importance, that the highest CPI corresponds to the modality *Higher education, except doctorate*, which reaches a value of 95% and low gross and net change indices.

The remaining modalities present CPI slightly over 90% and not too high net and gross change indices.

In order to compare general quality of the four characteristics previously analysed, table 13 presents the global consistency index (G.C.I.) thereof. We observe that for the characteristics *age*, *marital status* and *nationality* the GCI exceeds 99%; the *level of training* is the one which presents the worst index with 91.1%.

13. Global consistency indices

Characteristic	G.C.I.
Age	99.35
Marital Status	99.05
Nationality	99.57
Educational level	91.65

If we focus on table C.4 of the annex we observe that the population transfers between the different modalities of the characteristic *level of training* are not very significant, just as for the last two years. Therefore, the only transfer of some importance is the one which occurs between the modalities *Illiterate* and *Primary education*, given that of the people who in R.I. were classified as *illiterate* there is 16.5% who in O.I. were classified in the modality *Primary education*.

The least relevant transfer of people between the different modalities of *level of training* is in accordance with the improved indicators of this characteristic.

Conversely, there is a certain trend whereby persons raise their social status, stating a higher level of studies in R.I. than in O.I., it seems that this has disappeared for good as there are five consecutive years (2007-2011) in which this has been broken as can be seen for 2011 in table 14.

14. Persons with a different educational level in the two interviews

Educational level	No. of cases
Higher in R.I.	118
Higher in O.I.	189

6.2.2. RELATIONSHIP WITH ECONOMIC ACTIVITY

The results obtained for this characteristic in 2011 are presented in tables C.5 and I.5 for the total population aged 16 years old and over, C.6 for males aged 16 years old and over and C.7 for females aged 16 years old and over.

For the total population aged 16 years old and over, the percentages identically classified for the modalities *active*, *employed* and *inactive stand at over 96%*, with the three modalities furthermore presenting quite small net and gross change indices.

Of the different submodalities of the modality *inactive*, *another situation* and *disabled* present the worst indicators, these also being the least important ones quantitatively, specially the first one.

The modality *unemployed*, which systematically presented one of the lowest CPIs, had been gradually improving over the last few years which attained a value of approximately 94% in 2010; in 2011, the CPI of this modality has decreased reaching around 87%, which indicates that the upward trend of the previous years has been broken. As for negative bias, it can be observed in table I.5 that this is not so high, just as the gross change index.

This modality is traditionally one of the most difficult to collect, since in order to establish the condition of *unemployed*, it is necessary to respond to an extensive set of questions, which may give rise to discrepancies between the two interviews.

Chart 15 shows the population transfers between the *unemployed persons* modality and the other two (*employed* and *inactive persons*), expressed as a percentage of the R.I. total in the former. We can see that, of those classified as *unemployed persons* in R.I., 1.7% were classified as *employed* and 11.6% as *inactive persons* in O.I. Among the latest ones, most were devoted to the housework.

15. Percentage distribution of unemployed persons in R.I., by their situation in O.I.

Situation in O.I.	Percentage
Employed persons	1.17
Unemployed persons	93.71
- Seeking first job	6.76
- Have worked previously	86.95
Inactive persons	5.13
- Students	0.47
- Homemakers	2.80
- Other inactive persons	1.86

The global consistency indices for the characteristic *relationship with economic activity* and its main modalities are presented in table 16.

16. Global consistency indices

Characteristic	G.C.I.
Relationship with economic activity	98.48
- Men	99.03
- Women	98.18
Active persons	99.41
- Men	99.81
- Women	99.03
Inactive persons	95.53
- Men	97.19
- Women	94.84

The global consistency index of the *relationship with economic activity* has been calculated only considering its main modalities (*active* and *inactive persons*), reaching a value of 97.9%.

The global consistency index is greatest in the *active* group than in the *inactive* one, as is usual, undoubtedly due to difficulties arising from classifying persons into groups that are not mutually exclusive within the *inactive* group, such as disabled persons, retired persons and homemakers. By sexes, we observe that the GCI is somewhat higher when corresponding to men than that corresponding to women, except for the group of active persons.

Transfers of people between the most important modalities of *inactive persons*, within the group considered as such in both interviews, are still little significant.

6.2.3. ECONOMICALLY ACTIVE POPULATION

The economically active population is composed of those persons aged 16 years old or more who have a job in the reference week of the survey and those other who, since they do not have a job, are looking for one or are waiting to start one.

For this group of persons, the following characteristics are studied: *age, sex, marital status, educational level, professional situation, occupation and branch of activity*. Results are presented in tables C.8 to C.14 and in tables I.6 to I.8 (the latter correspond to the last three characteristics) of the Annex.

The global consistency indices for the characteristic can be seen in table 17.

17. Global consistency indices for the economically active population

Characteristic	G.C.I.
Age	99.68
- Men	99.90
- Women	99.88
Marital status	98.83
- Men	99.05
- Women	99.15
Educational level	90.78
- Men	90.29
- Women	91.84
Professional situation	96.59
Occupation	90.70
Branch of activity	93.80

On comparison of the *educational level* and *marital status* indices with these same characteristics for the population aged 16 years old or over (see table 13), we can see that they are greater for this population than for the active population, particularly in the case of educational level. Conversely, the G.C.I. for the characteristic *age* is somewhat larger in the case of the active population.

The global consistency index for the characteristic *professional situation* stands at 97.1%. This is influenced by the good quality of the indices in the modality *wage-earners* (see table I.6 of the Annex), which includes approximately 85% of those persons classified by this characteristic. The other modalities except *businesspersons without employees*, are not very important at all and correspond to the same worst indicators.

As for the characteristic *occupation* it can be observed that the overall consistency index attains a value of almost 92%, a value slightly over that obtained in 2010. Nevertheless, its quality indicators (see table I.7) are generally

worse than those for other characteristics assessed, due to the actual complexity in its classification.

In table I.7 it can be seen that the lowest CPI corresponds to *Senior government officials and executive directors*, with 80% and the highest corresponds to *Agricultural and fishing labourers*, which attains 96.4%.

As for bias (NCI), it can be seen that they are small, while gross change indices can be classified as acceptable, as their highest value, corresponding to the modality *Management of companies and the public administration*, is 40%.

For the characteristic *activity branch* the overall consistency index presents a value of 95%, that is, 1% over that of 2010. This seems to confirm the fact that the implantation in 2009 of the new classification of economic activities (CNAE-2009) has had a positive effect on the indicators of this characteristic.

The modality presenting the lowest CPI (see table I.8 of the Annex) is Water supply, sewerage, waste management and remediation activities, whose CPI stands at 84.2%, whilst as can be seen there are four which present a CPI of 100%. The indices of net and gross change can be qualified, in general, as moderate.

6.2.4. EMPLOYED POPULATION

The employed population is composed of all persons aged 16 years old or over who, in the reference week, had a job working for others or carried out a freelance activity, even if they did not work during the aforementioned week, or only did so partially for some reason. For this group of persons, the following characteristics are studied: *hours worked in the main activity*, *number of hours worked equal to or different than usual*, *reasons for working a different number of hours than usual* and *time that they have been working in their current job*. In addition, for employed persons the *type of contract* characteristic is studied, and for employees with a temporary contract, *its duration by public or private sector*. The results are shown in tables C.15 to C.20 of the Annex.

18. Global consistency indices

Characteristic	G.C.I.
Hours worked in the main job	90.72
No. of hours worked equal to or different than usual	96.93

Overall consistency indices for the first two characteristics are presented in table 18; it can be noted that both have increased slightly compared to values for 2009.

For the characteristic *hours worked in the principal job* the modality presented by the highest CPI is that of *No hour*, which attained a value of 97.4% (see table I.9 of the Annex). Conversely, the modality with the lowest CPI is *Do not know*, with 64.1% which is also the one with the highest bias and GCI.

Table C.16 of the Annex includes *employed persons according to whether they worked a number of hours equal to or different than usual*. It may be observed therein that, of the total employed persons classified by the number of hours worked, 76.5% are classified in R.I. in *worked the same number of hours*. We also notify that where less people are classified in E.R. is in the heading *worked more hours*, which represented 2.1%.

Table I.10 of Annex shows the quality indicators for this characteristic, the best ones corresponding to persons who *worked an equal number of hours*, with small net and gross change indices and with a CPI standing at almost 99.2%. The worst gross change index corresponds to the heading *worked more hours* and the worst bias to *worked less hours*.

With regard to *reasons for working a different number of hours than usual*, it is important to emphasise that persons classified as having worked a greater number hours than usual are so few (see table 17 of the Annex) that they are not worth remarking upon.

19. Reasons to work fewer hours than usual (P.I.C.)

Reason	P.I.C.
Holidays, leave, bank holidays	99.44
Illness, accident or temporary incapacity	97.30
Other reasons	82.76

As far as those employed persons working fewer hours than usual are concerned, 69% were classified in the modality *holidays, leave, public holidays*, there corresponding to this a fairly high CPI, as can be seen in table 99.4. This table only shows the three modalities into which a significant number of persons have been classified (see table C.17 of the Annex).

20. Percentage distribution of the situation of the employed persons in O.I., who, according to R.I., worked the same number of hours as usual that week

Situation in O.I.	Percentage
Does not know the number of hours worked	1.06
Worked the same number of hours as usual	98.16
Worked a different number of hours than usual	0.77
- Worked fewer hours than usual	0.58
Holidays, leave, bank holidays	0.10
Maternity leave or extended leave of absence	0.10
Illness, accident or temporary incapacity	0.10
or economic reasons	0.00
Labour force adjustment plan	0.00
Strike or labour conflict	0.00
Other reasons	0.29
Does not know	0.00
- Worked more hours than usual	0.19
Variable or flexible work schedule	0.00
Overtime	0.00
Other reasons	0.10
Does not know	0.10

Chart 20 shows the percentage distribution of the situation, according to O.I., of those employed persons who, according to R.I., worked an equal number of hours to in the week. We can see that 98.2% of these were classified in the same way in O.I., in other words, they also worked an equal number of hours to usual in O.I. 0.58% worked in E.O. less hours than normal mostly cases for *other reasons*. Another 0.19 per cent worked more hours than usual.

With regard to the characteristic *time that they have been working in their current job*, table 21 shows the percentages of those identically classified. The modality which presents the best CPI is *6 years or more* (98.5%), which is also the one in which 60% of employees are classified by this characteristic in E.R. The remaining modalities also show relatively high CPI, since it exceeds 92% in all of these. The overall consistency index is 97.3% which maintains the level attained in 2009.

21. Employed persons by the time working in the current job (P.I.C.)

Modality	P.I.C.
Less than 3 months	94.74
From 3 months to less than 6 month	92.31
From 6 months to less than 1 year	96.72
From 1 year to less than 2 years	97.30
From 2 years to less than 3 years	95.83
From 3 years to less than 6 years	95.45
6 years or more	98.47

Within the employed persons, *wage-earners* are all persons working for a public or private company and receiving remuneration in return, whether in cash or in kind.

Tables C.19 and C.20 of the Annex show the results of characteristics *wage-earners by sex and type of contract or labour relationship* and *wage-earners with a temporary contract, by public or private sector, and its duration*. The CPI for both characteristics are shown in tables 22 and 23, respectively.

22. Type of contract or labour relationship (P.I.C.)

Modality	P.I.C.
Indefinite duration	99.22
- Permanent	100.00
- Discontinuous	100.00
Temporary duration	96.92
- Temporary due to production circumstances	94.29
- Apprenticeship, training or internship	88.89
- Seasonal	85.00
- In the trial period	100.00
- Covering the absence of another worker	93.94
- From a project or service	93.65
- Another type	52.17
- Does not know	66.67

Within the characteristics *type of contract or labour relationship*, we can see that the modality *indefinite duration* shows higher CPI, in general, than the modality *temporary duration*, continuing the trend of previous years. The submodalities *indefinite duration* present in general higher CPI than those corresponding to *temporary duration*, while the latter are, except for *work or service*, *temporary because of production, covering another' employee's absence* and *seasonal* and of less quantitative importance.

The GCI of the characteristic *type of contract or work* relationship attains a value of 96.3% for which reason it has increased again somewhat in relation to 2009.

As far as the characteristic *duration of the temporary contract is concerned, by public or private sector*, the global consistency index stands at 88.9%, a value somewhat higher than the one obtained in 2009.

23. Duration of the temporary contract (P.I.C.)

Duration	P.I.C.
Public sector	95.59
- One day	-
- From 2 days to less than 1 month	100.00
- 1 to 3 months	100.00
- 4 to 11 months	100.00
- From 1 year to less than 3 years	93.33
- 3 years or more	100.00
- Does not know, but less than 1 mor	-
- Does not know, but more than 1 mc	83.33
- Does not know	100.00
Private sector	97.83
- One day	-
- From 2 days to less than 1 month	100.00
- 1 to 3 months	90.32
- 4 to 11 months	97.06
- From 1 year to less than 3 years	100.00
- 3 years or more	100.00
- Does not know, but less than 1 mor	0.00
- Does not know, but more than 1 mc	85.71
- Does not know	92.00

In the first place, it is necessary to say that there few persons to classify according to this characteristic, the majority of whom are in the modality *private sector*, with 73%, as shown in table C.20 of the Annex. Therefore, the modality *public sector* is of very little importance in quantitative terms, therefore the CPI of its submodalities, whose values can be seen in table 23, are of very little significance.

The CPI for the modality *private sector* are more significant and their values may likewise be seen in table 23. In general it can be said that they are high as in various of the submodalities this attains 100%, corresponding to the lowest value, 85.7%, to the submodality *Do not know but more than 1 month*.

6.2.5. UNEMPLOYED POPULATION

Unemployed persons are regarded as all those aged 16 years old or over who, in the reference week, simultaneously meet the following conditions:

- Do not have work.
- Are seeking work, or if not, it is because they have already found a job, which they will be starting at a date subsequent to the reference week.
- Are available to work.

From this group of active persons, by the repeat interview procedure, the quality of the characteristics *type of unemployed person*, distinguishing between males and females, *economic sector* and *time that they have been seeking work* (tables C.21 to C.23 of the Annex) is assessed.

In *type of unemployed person*, a distinction is made between those seeking their first job and those who have worked previously.

Table 24 shows the net change indices for unemployed people according to sex and type of unemployed person; it can be observed that in the case of men there is no bias at all and that in the case of women they are not very high. On the other hand, in Table 25 it can be seen that unemployed men have an overall consistency index of 100%; that for women is also very high, almost 99%,

24. Unemployed persons, I and type (N.C.I.)

<u>Sex/ type of unemployed person N.C.I.</u>	
Men	
- Total	0.00
- Seeking first job	0.00
- Have worked previously	0.00
Women	
- Total	0.00
- Seeking first job	10.53
- Have worked previously	-1.26

In terms of the *economic sector*, its G.C.I. reaches a value of 95% (table 996), thereby experiencing a notable increase with regard to that obtained in 6. This improvement is surely due to 2009.

Finally, for the implantation of the new CNAE-2009.

We have to stress that, finally, the new improvement experienced in the capacity of the characteristic *job search time* the overall consistency index is 95.1%, somewhat lower than that obtained in 2009.

25. Global consistency indices

Characteristic	G.C.I.
Type of unemployed person	99.50
- Men	100.00
- Women	98.88
Economic sector	96.59
Time spent on the job search	95.08

6.2.6 CONCLUSION

On analysing previous tables, it has been possible to see that, even though there are differences between the different characteristics, the quality of data from the APS remains within fairly acceptable limits. It is worth highlighting that the O.I.-R.I. comparison is performed by computer, once both the O.I. and the R.I. data have been submitted to different filtering and imputation processes. The only difference in processing O.I. and R.I. data stems from the fact that, whereas some O.I. data is imputed by means of a random procedure (DAY), in the R.I. data no random imputation procedure is used.

Conversely, any difference between O.I. and R.I. is counted as a content error, although it may be due to lapses of memory or to discrepancies in interpreting the question, where the informant is not the same in the two interviews. Similarly, in some characteristics whose modalities are not mutually exclusive, classification is difficult to specify in practice.

6.3 Other applications of the assessment interview

6.3.1. STUDY OF THE INFLUENCE OF THE INFORMANT ON THE QUALITY OF THE RESULTS

In order to analyse the possible influence on the quality of the results of the fact that the informant has been the same or different in the two interviews (O.I. and R.I.), the joint O.I.-R.I. information of the four quarters from the four quarters and relating to the population aged 16 years old and over, has been separated into two blocks, one corresponding to the dwellings in which the informant was the same in both interviews and another corresponding to the dwellings in which the informant was different therein.

In order to study the influence of this variable, the characteristics *relationship with economic activity* and *educational level* have been selected, since they are regarded as being of great special interest.

To this end, for each of the aforementioned blocks, corresponding coincidence tables have been prepared for each of said characteristics and their corresponding quality indicators have been calculated. The results obtained for the *relationship with economic activity* can be seen in tables 26 to 28, and for *educational level* in tables 29 to 31.

26. Persons aged 16 years old and over, according to O.I. and I by relationship with economic activity. Same informant

Classification by R.I.	Classification according E.O.	Active persons				Inactive persons	
		Total	Employed persons	Unemployed persons	Seeking first job		
Total persons	2,770	1,401	1,088	313	20	293	1,369
No evidence of activity	3	-	-	-	-	-	3
Total classified	2,767	1,401	1,088	313	20	293	1,366
Active persons							
Total	1,407	1,387	1,081	306	20	286	20
Employed persons	1,086	1,080	1,077	3	-	3	6
Unemployed persons							
Total	321	307	4	303	20	283	14
Seeking first job	19	18	-	18	18	-	1
Have worked previously	302	289	4	285	2	283	13
Inactive persons	1,360	14	7	7	-	7	1,346

27. Persons aged 16 years old and over, according to O.I. and I by relationship with economic activity. Different informant

Classification by R.I.	Clasificación según E.O.	Active persons				Inactive persons	
		Total	Employed persons	Unemployed persons	Seeking first job		
Total persons	914	496	393	103	10	93	418
No evidence of activity	1	-	-	-	-	-	1
Total classified	913	496	393	103	10	93	417
Active persons							
Total	506	490	390	100	9	91	16
Employed persons	398	390	389	1	-	1	8
Unemployed persons							
Total	108	100	1	99	9	90	8
Seeking first job	10	9	-	9	9	-	1
Have worked previously	98	91	1	90	-	90	7
Inactive persons	407	6	3	3	1	2	401

Regarding the first of these characteristics (*relationship with activity*), in light of the figures from table 28 it can be said that there are no major differences between the indicators in both cases as they are quite similar with both kinds of informant, although in all cases somewhat higher in the case of the same informant (the greatest difference, approximately three points, is given for the CPI of the unemployed).

With regard to population transfers between unemployed and inactive persons, these are greater in the case of the same informant, since almost 7.4% of those classified as unemployed in R.I. are classified as inactive in O.I., this percentage being 4.4% in case the informant is the same.

28. Quality indicators. Relationship with economic activity with the same or a different informant

Relationship with economic activity	Percentage of identically classified		Net Change Index		Global Consistency Index	
	Informant		Informant		Informant	
	Same	Different	Same	Different	Same	Different
Active persons	98.58	96.84	-0.43	-1.98	-	-
Employed persons	99.17	97.74	0.18	-1.26	-	-
Unemployed persons	94.39	91.67	-2.49	-4.63	-	-
Inactive persons	98.97	98.53	0.44	2.46	-	-

With these results, we may conclude that the fact that the informant is the same or different in the two interviews does not have a significant influence on the classification of the population according to the relationship with economic activities, although the quality indicators, as has been seen, are better when the informant is the same in O.I. and in R.I.

Charts 29 and 30 present the persons classified in O.I. and R.I. according to the educational level for the same and different informants. We can observe that for the modality *doctorate* very few people are classified for which reason their indicators are not at all significant. For this reason we will not consider this when performing the comparative analysis for the characteristic *level of training*.

29. Persons aged 16 years old and over according to O.I. and R.I., by educational level. Same informant

Classification according to R.I.	Classification according to O.I.		Educational level					
	Total	Illiterate	Primary education	Secondary education	First stage	Second stage	Higher education, except doctorates	Doctorat
Total persons	2,770	94	987	691	483	510	5	
Does not know educational level	6	4	2	-	-	-	-	-
Total classified	2,764	90	985	691	483	510	5	
Illiterate	94	81	13	-	-	-	-	-
Primary education	1,003	9	915	73	6	-	-	-
Secondary education								
- First stage and corresponding training and labour insertion	668	-	47	604	15	2	-	-
- Second stage and corresponding training and labour insertion	485	-	9	12	446	18	-	-
Higher education, except doctorates	508	-	1	2	16	489	-	-
Doctorate	6	-	-	-	-	1	5	

30. Persons aged 16 years old and over according to O.I. and R.I., by educational level. Different informant

Classification according to R.I.	Classification according to O.I.		Educational level					
	Total	Illiterate	Primary education	Secondary education	First stage	Second stage	Higher education, except doctorates	Doctorat
Total persons	914	19	297	242	162	191	3	
Does not know educational level	-	-	-	-	-	-	-	-
Total classified	914	19	297	242	162	191	3	
Illiterate	24	17	6	1	-	-	-	-
Primary education	317	2	280	32	2	1	-	-
Secondary education								
- First stage and corresponding training and labour insertion	227	-	8	206	12	1	-	-
- Second stage and corresponding training and labour insertion	154	-	1	3	143	7	-	-
Higher education, except doctorates	189	-	2	-	5	182	-	-
Doctorate	3	-	-	-	-	-	-	3

If we analyse the results obtained, observing the indicators shown in table 31, we can see that in all modalities they are better when the informant is the same. The greatest differences are registered in the illiterate modality. The GCI is three points higher in the case of the same informant.

31. Quality indicators. Educational level with the same or a different informant

	Percentage of identically classified		Net Change Index		Global Consistency Index	
	Informant		Informant		Informant	
	Same	Different	Same	Different	Same	Different
Educational level	-	-	-	-	91.90	90.92
Illiterate	86.17	70.83	-4.26	-20.83	-	-
Primary education	91.23	88.33	-1.79	-6.31	-	-
Secondary education						
- First stage and corresponding training and labour insertion	90.42	90.75	3.44	6.61	-	-
- Second stage and corresponding training and labour insertion	91.96	92.86	-0.41	5.19	-	-
Higher education, except doctorates	96.26	96.30	0.39	1.06	-	-
Doctorate	83.33	100.00	-16.67	0.00	-	-

As for population transfers between modalities (see tables 29 and 30), the most important because of their impact from the quantitative point of view is what occurs between *primary education* and *secondary education, first stage*. This transfer is most important in the case of a different informant as 10.8% of people classified in en E.R. in *primary education* are classified in E.O. in *secondary education, first stage*, while when the informant is the same; this percentage is 7.6%.

With these results it cannot be stated that the fact that the informant is the same or different in both interviews has a decisive effect on the classification of the population according to the *level of training* attained, but when the informant is the same the results are slightly better, just as occurred in the case of the *relationship with the activity*.
